World Small Hydropower Development Report 2022

Consolidated Version

Disclaimer

The World Small Hydropower Development Report 2022 is jointly produced by the United Nations Industrial Development Organization (UNIDO) and the International Center on Small Hydro Power (ICSHP) to provide development information about small hydropower.

The opinions, statistical data and estimates contained in signed articles are the responsibility of the authors and should not necessarily be considered as reflecting the views or bearing the endorsement of UNIDO or ICSHP. Although great care has been taken to maintain the accuracy of information included in the document, neither UNIDO and its Member States, nor ICSHP assume any responsibility for consequences that may arise from the use of the material.

This document has been produced without formal United Nations editing. The designations employed and the presentation of the material in this document do not imply the expression of any opinion whatsoever on the part of the UNIDO Secretariat concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries, or its economic system or degree of development. Designations such as 'developed', 'industrialized' and 'developing' are intended for statistical convenience and do not necessarily express a judgment about the stage reached by a particular country or area in the development process. Mention of firm names or commercial products does not constitute an endorsement by UNIDO.

Foreword

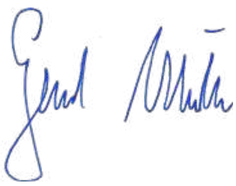
by **Gerd Müller, UNIDO Director General** for World Small Hydropower Development Report 2022 Executive Summary

The COVID-19 pandemic caught the world unprepared for a complex, systemic challenge of such a scale. Livelihoods, economic progress, and social stability have been severely impacted worldwide. The COVID-19 pandemic has also slowed progress towards sustainable energy goals. In such a critical moment when multiple crises are coming together, we need a decisive collective effort to follow through on the goals the world community agreed on to build sustainable energy systems. We must make sure that renewable energy development is a top priority at all levels of decision-making.

In the face of this challenge, it is especially critical to continue to collect and share knowledge about the various renewable energy technologies. Small hydropower is one of such solutions. It has long played a key part in providing access to sustainable and reliable electricity around the world. Small hydropower is a simple, adaptable and low-cost technology, which makes it particularly suitable for remote and marginalized communities. When planned with environmental and socio-economic aspects in mind, it provides access to sustainable renewable energy, the basis for any development which also empowers communities, improves livelihoods and is the basis for more development opportunities. Small hydropower offers one answer to many questions posed by the pandemic, climate crisis and energy transition for achieving the commitments under the Paris Agreement.

Over 60 per cent of global small hydropower potential remains untapped. There are still vast opportunities across the globe to use it for the benefit of local communities and the planet. In order to support policy-makers, communities, potential developers and other stakeholders interested in developing small hydropower projects, the United Nations Industrial Development Organization (UNIDO) partnered with the International Center on Small Hydro Power (ICSHP) to launch the fourth edition of the World Small Hydropower Development Report. The first three editions have shown that the report is a much-needed global knowledge product on small hydropower. I am proud that that this is already the fourth edition of the report and that UNIDO and ICSHP are continuing this important work of knowledge gathering and distribution. The valuable content of the current edition is an outcome of a collective effort of more than 200 experts and contributing organizations from all over the world. The production of this comprehensive report would not have been possible without generous support and intellectual leadership from the Ministry of Water Resources of the People's Republic of China and ICSHP.

I am confident that this report will contribute to the global effort to build sustainable energy systems that will help mitigate the climate crisis and empower communities.



Acknowledgements

The World Small Hydropower Development Report 2022. was prepared under the overall guidance of Tareq Emtairah, Director of the Division of Decarbonization and Sustainable Energy, Petra Schwager-Kederst, Chief of the Division of Climate and Technology Partnerships at the United Nations Industrial Development Organization (UNIDO) and LIU Deyou, Director General of the International Center on Small Hydropower (ICSHP).

The preparation of this thematic publication was headed by LIU Heng, Senior Technical Advisor at UNIDO and consulted by HU Xiaobo, Chief of the Division of the Multilateral Development at ICSHP. The work was coordinated by Oxana Lopatina at ICSHP and Eva Krēmere at UNIDO. The publication is the result of three years of intense research work and was backed by a talented and indispensable team of researchers at ICSHP and a vast number of experts in the field of small hydropower

Executive Summary

Preface

Providing universal access to energy remains one of the most critical economic, environmental and development challenges facing the world today with over 700 million people, or 9.5 per cent of the global population, predominantly in rural areas, still lacking access to electricity in 2020.1 Access to reliable and affordable electricity has an immediate and transformative impact on the quality of life and is crucial to ensuring access to such basic services as healthcare and education. At the same time, in both developing and developed countries, the need for clean and sustainable sources of energy is growing more acute in the face of the climate crisis and environmental degradation. Sustainable renewable energy is, thus, a key building block towards both the broader development goals, including poverty eradication and public services provision, and climate crisis mitigation and prevention of environmental degradation.

As the lowest-cost renewable energy technology, hydropower remains integral to international efforts to fight the climate crisis and ensure a clean energy future. Small hydropower (SHP), due to its adaptability to the local needs and conditions and suitability for remote rural areas with low-density energy demand, has been at the centre of development strategies worldwide, whilst helping reduce greenhouse gas emissions and promoting greater energy independence. If effectively and sensitively planned, SHP projects can also offer opportunities for the empowerment of local communities, including the usually disadvantaged groups, such as women and youth, empowering them economically and contributing to progress towards greater equality.

In order to more effectively promote SHP as a renewable and rural energy solution and overcome existing barriers, it is essential to identify the development status of the technology across regions and engage stakeholders to share existing knowledge and experience. Prior to the first edition of the World Small Hydropower Development Report (WSHPDR) published in 2013, it was clear that a comprehensive reference publication for decision-makers, stakeholders and potential investors was needed. Today, the WSHPDR is the only global publication dedicated to the dissemination of in-depth information on SHP development.

For the fourth time, the United Nations Industrial Development Organization (UNIDO) and the International Center on Small Hydro Power (ICSHP), as the global knowledge leaders in the SHP sector, are continuing their partnership for the new edition of the report, the WSHPDR 2022. The new edition contains 20 regional chapters, 166 country chapters, 12 case studies, 3 thematic publications as well as a global database of existing and planned SHP plants. The WSHPDR 2022 is the result of an enormous collaborative effort between UNIDO, ICSHP and over 200 local and regional SHP experts from across the globe, including engineers, academics and government officials. The current edition of the Report aims not only to provide an update on the SHP status by country but also to expand on the first three editions by providing improvements in data accuracy with enhanced analysis and a more comprehensive overview of the sector by country.

What is new?

Compared to the previous editions, the *WSHPDR 2022* offers a more detailed analysis of the SHP status by country, covering such aspects as operational, planned and potential SHP projects, cost of SHP development, financial mechanisms available for SHP projects, effects of the climate crisis on SHP as well as factors favouring further SHP development. Furthermore, the new edition includes three thematic publications addressing the topics of gender equality, youth involvement and climate change from the perspective of SHP as well as the first global database of developed and planned SHP projects by country. Finally, the current edition includes a collection of new case studies illustrating successful examples of SHP implementation, focusing on the social benefits of SHP projects, as well as new technological solutions available.

Global overview

According to the *WSHPDR 2022*, the global installed SHP capacity for plants of ≤10 MW is estimated at approximately 79.0 GW and the total known potential for SHP ≤10 MW (including developed capacities) is estimated at 221.7 GW. Thus, despite the appeal and benefits of SHP solutions, much of the world's SHP potential remains untapped (64 per cent). It should be noted that for a number of countries, including those with very developed SHP sectors (for example, India), data on SHP of ≤10 MW are not available due to the use of different local definitions. Therefore, the global installed and potential capacity can be assumed to be somewhat higher than the reported totals.

Compared to the *WSHPDR 2019*, SHP installed capacity (≤10 MW) increased by 1 per cent (Figure 1). At the same time, the estimated SHP potential decreased by 3 per cent (Figure 2) based on more accurate data obtained for a number of countries, including Norway, Turkey and the Philippines, as well as due to the lack of data on SHP of ≤10 MW for some other countries.

Figure 1.
Global Installed Capacity of Small Hydropower of ≤10 MW in the WSHPDR 2013/2016/2019/2022 (GW)

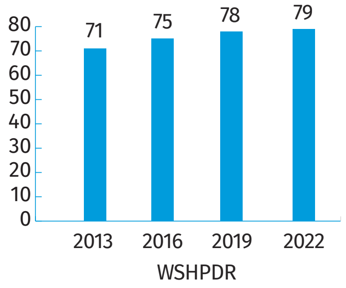

Figure 2.
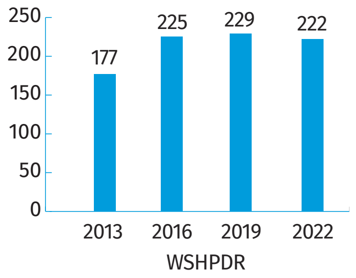
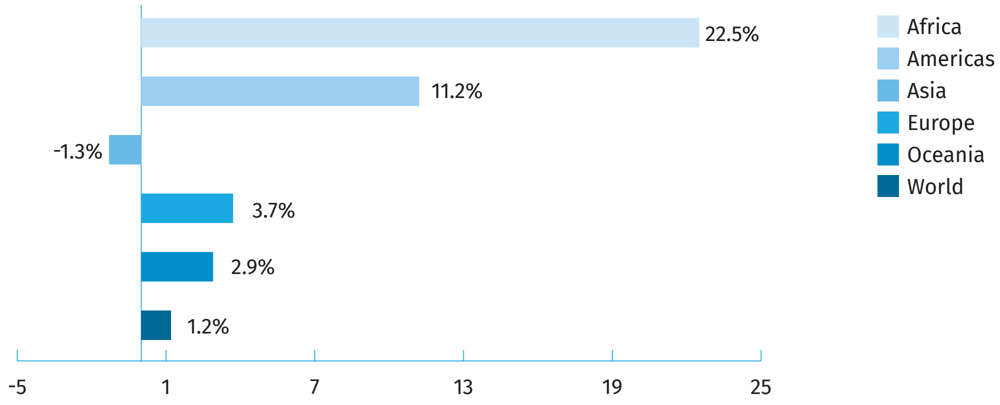
Global Potential Capacity of Small Hydropower of ≤10 MW in the WSHPDR 2013/2016/2019/2022 (GW)



The greatest relative increase in installed SHP capacity compared to the *WSHPDR 2019* is reported for Africa with an increase of almost 23 per cent (Figure 3). The Americas, Europe and Oceania have also seen an increase in installed SHP capacity of approximately 11 per cent, 4 per cent and 3 per cent, respectively, compared to the previous edition of the Report. In absolute terms, the largest increase in installed capacity is reported for Europe at 734 MW, followed by the Americas with 698 MW and Africa with 134 MW of new capacity. Conversely, the reported SHP installed capacity of Asia decreased by approximately 1 per cent, as a result of an updated estimation for Turkey as well as a lack of data for the 10 MW definition for some countries.

Figure 3.
Change in Installed Small Hydropower Capacity between the WSHPDR 2019 and the WSHPDR 2022 by Continent (%)



SHP (of ≤10 MW) represents approximately 1 per cent of the total electricity installed capacity of the countries included in this Report and 6 per cent of their total installed hydropower capacity. Asia continues to have the largest installed capacity and potential for SHP of ≤10 MW, accounting 64 per cent and 63 per cent of the global total, respectively (Figures 4 and 5). Europe has the highest percentage of SHP development (52 per cent for SHP ≤10 MW), with Western Europe having 83 per cent of its known potential already developed. The largest known undeveloped SHP potentials are concentrated in Central Asia, Eastern Asia and South-Eastern Asia (Figure 6).

Figure 4.
Share of Global Installed Small Hydropower Capacity of ≤ 10 MW by Continent (%)

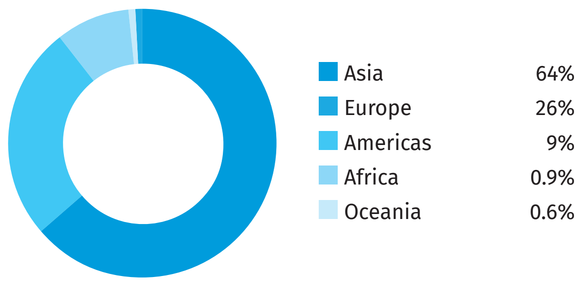


Figure 5
Share of Global Small Hydropower Potential of ≤ 10 MW by Continent (%)

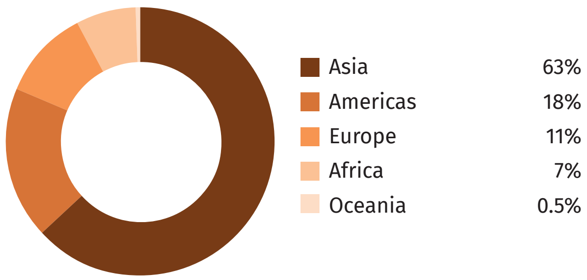

Figure 6.
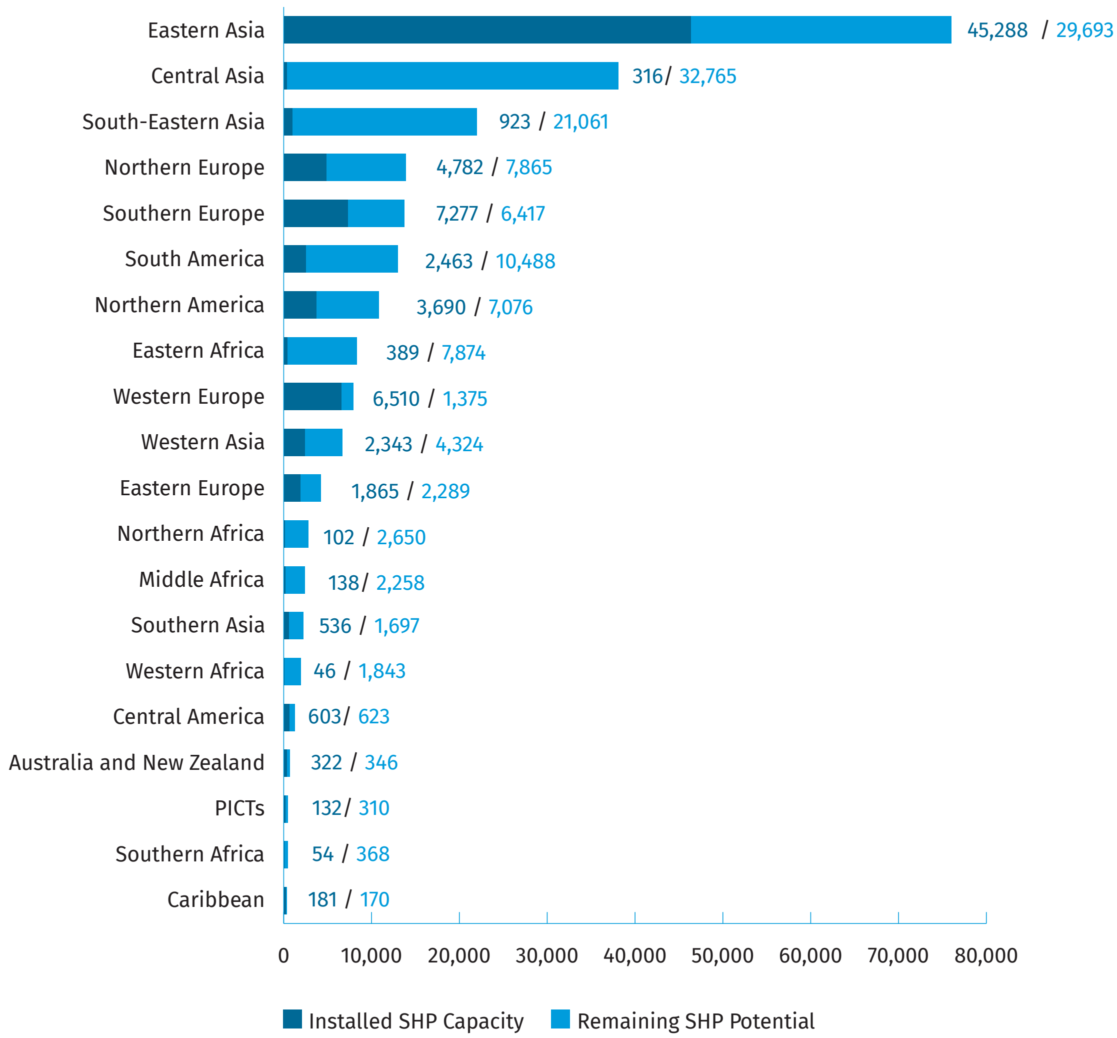
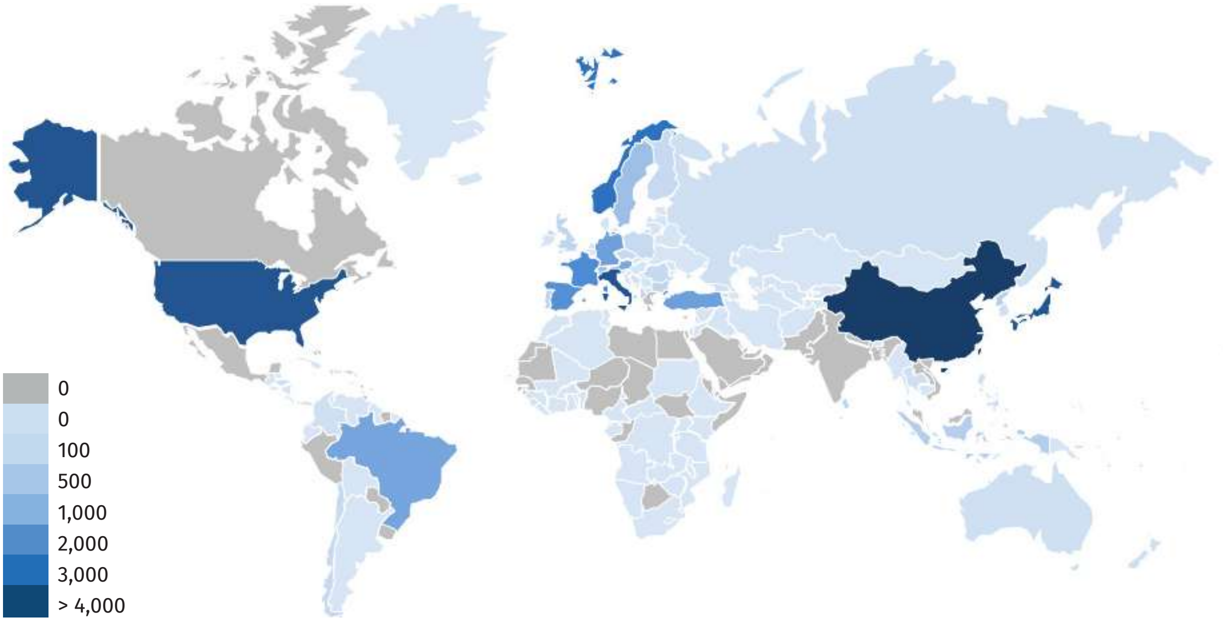
Developed and Remaining Small Hydropower Potential of ≤10 MW by Region (MW)



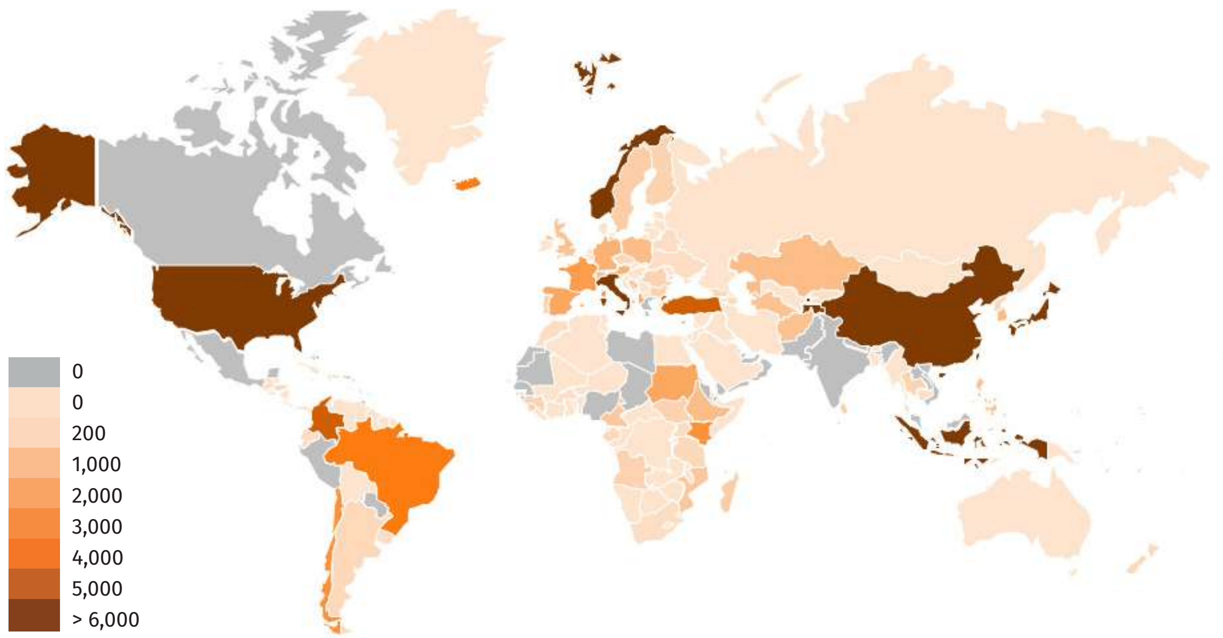
China continues to dominate the global SHP landscape, with 53 per cent of the world's total SHP installed capacity (definition of ≤10 MW) and approximately 29 per cent of the world's total known SHP potential. In terms of installed capacity, China is followed by the United States of America (USA), Italy, Japan and Norway. Together, these five countries account for almost 71 per cent of the world's total installed capacity of SHP ≤10 MW.

Figure 7.
Small Hydropower Installed Capacity of ≤10 MW by Country (MW)



Note: Highlighted in grey are countries without data on SHP of ≤10 MW or no SHP plants installed.

Figure 8.
Small Hydropower Potential Capacity of ≤10 MW by Country (MW)



Note: Highlighted in grey are countries without data on SHP of ≤10 MW.

Africa

SHP in Africa can be characterized as having a relatively low level of installed capacity but with considerable potential for development. Climatic and topographic characteristics vary tremendously across the continent, resulting in a large variance in SHP potential in the north and south as compared to the east and west. The total installed capacity of SHP ≤10 MW in Africa is 729 MW and the total estimated potential is 15,714 MW. This indicates that less than 5 per cent of the known SHP potential of ≤10 MW has been developed so far.

Eastern Africa has the highest installed capacity of SHP of ≤10 MW on the continent (53 per cent of the continental total), followed by the Middle and Northern Africa regions. The highest known SHP potential is also found in Eastern Africa (also 53 per cent of the continental total), while the lowest potential is found in Southern Africa. Of all the countries in Africa, Uganda has the highest installed capacity of SHP of ≤10 MW (108 MW), whereas Kenya has the highest estimated potential for SHP of ≤10 MW (3,000 MW).

Americas

Northern America and South America dominate the SHP landscape in all of the Americas, with Brazil and the USA being leaders in terms of installed capacity and the USA also dominating in terms of known SHP potential. Countries in the Caribbean region have significantly smaller estimated potential. However, further studies could reveal a greater potential in the region as well as in other countries in the continent.

The total SHP capacity in the Americas is 6,937 MW, while the total potential is estimated at 25,294 MW for SHP of ≤10 MW. Some countries with enormous expected SHP potential have not performed feasibility studies to determine their exact potential capacity. Mexico, for example, is a country that is suspected to have significant SHP potential but no studies have been conducted yet. At the same time, in the current edition, the continent's reported potential significantly decreased compared to the previous edition, which is primarily due to the re-estimation of the potential of Colombia. According to the available data, approximately 27 per cent of the known SHP potential capacity in the Americas has been developed.

Asia

Asia has vast SHP resources, which are, however, unevenly distributed across the continent. The total installed SHP capacity of Asia is 50,406 MW and the total estimated potential is 139,946 MW (for SHP of ≤10 MW). This indicates that approximately 36 per cent has so far been developed. The decrease in reported SHP installed capacity in comparison with the *WSHPDR 2019* is primarily due to the re-estimation of the installed capacity data for Turkey.

China dominates not only the SHP landscape in Asia but also globally, accounting for over 83 per cent of the continent's installed capacity and 45 per cent of the known potential for SHP of ≤10 MW. SHP development is one of the major priorities for countries in Asia. The key motives for SHP development on the continent are to decrease dependence on energy imports and fossil fuels and to improve access to electricity, especially in rural areas.

Europe

Europe has a long history of SHP development, which has enabled it to reach a high level of installed capacity and potential development. The overall installed capacity of SHP of ≤10 MW in the region is 20,434 MW, while the potential capacity is estimated at 39,607 MW, indicating that 52 per cent of known potential has been developed. The increase in SHP installed capacity in comparison to the *WSHPDR 2019* is mainly due to the new capacities added in Norway, Italy and Albania.

With a wide variety of climates and landscapes in the continent, SHP potential varies across the regions. The greatest remaining potential is concentrated in Northern Europe, primarily in Norway. Italy is the leader in the continent in terms of installed capacity of SHP of ≤10 MW, followed by Norway and France.

Oceania

Oceania is the smallest region in terms of the number of countries included in this Report as well as in terms of installed and potential SHP capacity. The total installed capacity of SHP of ≤10 MW amounts to 454 MW, indicating an increase of 3 per cent in comparison to the *WSHPDR 2019*. The total estimated potential is 1,106 MW, thus, approximately 36 per cent has so far been developed.

The Oceania region is very diverse in terms of SHP potential. While all the countries receive enough rainfall to merit constant SHP production, only a few of the islands have mountainous terrain, which is usually a key factor for SHP potential. The Australia and New Zealand region is the richest area regarding SHP potential in Oceania, however, further SHP development is not foreseen in the region. On the other hand, the Pacific Island Countries and Territories (PICTs) are mostly flat islands and have little or no SHP potential, thus, making topography the key barrier.

Thematic publications

Compared to the previous editions, the *WSHPDR 2022* has been expanded with three thematic publications exploring three important aspects of SHP development: gender empowerment, youth involvement and climate change. The social and environmental aspects of SHP development often do not receive the needed attention and the particularities of the SHP technology can be lost in more general analyses devoted to renewable energy technologies or hydropower. These three publications aim to address this gap in the understanding of the SHP sector by exploring the specificity of the SHP technology in terms of how it both impacts and is impacted by gender dynamics, youth representation and climate change. The information gathered in these publications is based on literature reviews and expert and stakeholder interviews and is intended to highlight key themes within each topic as well as outline some of the most important directions for further research and analysis.

"How SHP empowers women and closes gender gaps and can do more"

Empowering women and girls and closing gender gaps are critical to realizing sustainable development goals (SDG) and ensuring a good quality of life for all. The energy sector, and in particular, decentralized systems such as SHP can facilitate the achievement of these targets. SHP can provide not only sustainable energy but also a steady baseload, which can facilitate positive changes to women's lives in the communities in which SHP plants are constructed and also beyond these communities.

In countries with low levels of access to electricity, benefits of access to electricity from SHP plants for women can include reduced time poverty and drudgery due to the use of electric appliances for household chores and economic activities. This immediately improves women's welfare but can also have knock-on benefits when such time is invested in studying, income generation and other life-enhancing activities. SHP development can also create direct and indirect jobs, provide power for productive uses and income generation and improve the delivery of critical social services including education and health services. Making the gender approach part of project design and implementation is critical to ensuring that SHP projects help empower women and girls across the globe, and close gender gaps. This publication discusses some of the ways in which SHP development is empowering women and girls and closing gender gaps between women and men. Further, it discusses the barriers to women's participation in the SHP sector and makes some key recommendations for addressing these barriers.

"Prospects for youth in the small hydropower sector"

Young people around the world can play a key role in creating the change required for the transformation of the global energy system, thus, contributing to regional and international development aims, while at the same time finding and creating opportunities for their own professional and personal development. While much of the world's SHP potential remains untapped, the SHP sector offers great opportunities for young professionals and entrepreneurs to get involved in providing clean energy to communities across the world. The active participation of youth in SHP can play a vital role in achieving a sustainable energy system because young people can bring the creative and forward-oriented thinking that is needed for a rapid energy transition. At the same time, young people continue to face multiple barriers in accessing the required skills to get involved in the sector as well often do not receive the needed policy, institutional and financial support.

This publication explores different opportunities that exist for youth in the SHP sector, with examples from around the world. It also analyzes the main barriers that young professionals considering joining or transitioning to the sector face as well as existing challenges faced by young energy professionals, including young women, already involved in the SHP sector. The report also provides a list of recommendations on how to overcome the existing barriers.

"Small hydropower and climate change"

Hydropower has a dual relationship with the climate crisis — it helps mitigate the impacts of changing climate but is also subject to vulnerability because of its dependence on the hydrological regime, which is affected by climatic conditions. Hydropower projects help displace fossil fuel energy sources (particularly, oil, coal and biomass in the case of SHP) and limit global warming. At the same time, changes in runoff due to climate change can have an effect in the short term (days, months) and the long run with significant implications for the productive uses of SHP plants. Climate change also induces effects in other sectors that can cascade to SHP plant operations, with competing water uses and different requirements from the grid also affecting the operations of SHP plants. However, climate change will impact hydropower generation in different ways depending on the region. Moreover, size influences the project's role in mitigation and adaptation to climate change. Due to limited capacity to store water and control floods, run-of-river SHP plants are particularly vulnerable to changing hydrological patterns.

The current publication offers a synopsis of projected climate change impacts on SHP by region as well as makes recommendations on climate change adaptation measures to be considered for climate change-resilient SHP and indicates the key directions for further research on the topic.

Global SHP Database

As part of the new edition of the *WSHPDR* and in collaboration with local experts, UNIDO and ICSHP have created the first Global SHP Database, which aims to gather in one place and make easily accessible detailed information on SHP projects worldwide. The database consists of two sections: (a) existing SHP plants and (b) planned and potential SHP projects. Currently, it includes data from 129 countries and territories across five continents, listing 6,249 existing SHP plants and 8,860 potential and planned plants. The database is intended to serve as a source of information on the current status of SHP development by country as well as on projects that are under development or are available for investment.

The database is based on the most accurate data available, however, the completeness of data varies from country to country. Moreover, some countries have legal restrictions on sharing data on power plants publicly and, hence, these countries were not included in the database. This indicates that further efforts are required both on a local and international level, where this is possible, to compile detailed information on SHP projects to have a more complete understanding of the sector. It is hoped that the database can be further expanded in future editions.

Case studies

The case study section of the *WSHPDR 2022* comprises 12 case studies. The case studies share the best practices and experiences from a range of countries, highlighting the potential of SHP for productive use and community development. They demonstrate that SHP plants, when carefully planned and developed respecting the needs of communities and with regard to local capacities, infrastructure and environment, can provide a reliable and affordable source of electricity, revolutionizing the daily lives of communities, in particular in rural areas.

The section aims to provide real-life examples of benefits that communities can receive from SHP as well as the challenges encountered and solutions found during the implementation of SHP projects. Each case study includes a list of lessons learnt summarizing the factors that should be kept in mind while planning, developing and implementing SHP projects in order to ensure their success. This information might be particularly useful for decision-makers, students, engineers and company managers.

The case studies are gathered under the following three themes.

SHP for social and community development: Many people in the world still live without access to affordable, reliable and clean electricity. Lack of electricity is a significant barrier to human, social and community development, specifically impacting vulnerable groups, including women and young people. The case studies presented in this group (Brazil, Ghana, Japan, Kenya, Tanzania and Zambia) demonstrate the benefits that SHP can offer target communities. In particular, the discussed projects created employment opportunities, increased the standard of public service provision, improved security and education conditions. In these cases, SHP helped communities become more autonomous, stimulated local business and entrepreneurship and considerably improved life quality.

Technological solutions for SHP: SHP development and operation can be influenced by different factors, such as market, weather, site location and strict environmental regulations. A range of technical solutions exist that can help adapt the SHP technology to the local conditions and improve the control over different factors, making the SHP management more efficient and predictable. These include retrofitting of existing civil structures (Italy case), developing a compact run-of-river low-head hydropower concept (Hydroshaft), using innovative software solutions such as HYDROGRID's automated data-driven optimization for SHP cascades, intelligent operation control and dispatching systems for complementary power plants (China case), or Fichtner's Hybrid Configurator that helps design hybrid power plants and analyze their technical and financial impact.

Green SHP: Lack of appropriate regulation and control over SHP development can result in significant ecological impact including river dehydration, changed river ecology, reduced river connectivity and affected migratory fish and other aquatic species. Lack of sustainable practices, can also increase the risk of socio-environmental conflicts. To maintain the ecological safety of the sector, the future of SHP development should be in the form of green SHP, supported by regulations, guidelines, incentive policies and practices. The Ukraine case study outlines the importance of SHP construction and operation in line with the principles of ecological sustainability.

Conclusions & Recommendations

SHP is a mature and versatile technology, effective for providing access to clean and sustainable electricity both in the developing and developed world, particularly in rural areas. Through developing SHP, many countries have already taken steps — or are beginning to take steps — to alleviate poverty and increase access to electricity. SHP also helps developed nations achieve targets for advancing renewable energy and reducing greenhouse gas emissions.

The purpose of this edition of the *WSHPDR* is to illustrate the improvements achieved in the SHP sector across regions and the great positive impacts linked to SHP development. Since the publication of the first edition of the Report in 2013, the combined installed capacity of SHP in the world increased by 12 per cent reaching 79 GW. At the same time, known SHP potential is estimated at 221.7 GW. Thus, the data collected in the Report demonstrate that there is still room for improvement in the SHP sector in many parts of the world. Overall, despite the progress made in SHP development in the last few years, many of the barriers and, hence, recommendations for the further development of the sector remain similar to those listed in the previous editions of the Report.

The following recommendations for addressing the barriers to SHP development are provided as general recommendations and should not be considered comprehensive.

(a) Undertake detailed resource assessments

Developing countries should undertake detailed analyses of their SHP potential to lower development costs and encourage private investment. Developed countries would similarly benefit from undertaking detailed re-assessments of their SHP potential, accounting for new technologies, ecological conditions, regulations as well as the potential arising from the conversion of existing infrastructure and the rehabilitation of old sites.

(b) Develop appropriate policies and regulations

Policies and financial incentives already established for other sources of renewable energy should be extended to cover SHP, particularly emphasizing green technology, and clear targets for SHP development should be set. Such policies and incentives should be properly designed to account for the local conditions and draw on collaboration among agencies responsible for water resources, environment and electricity. Government agencies should also streamline the licensing process by creating a one-stop shop for standardized permits and contracts.

(c) Facilitate access to sustainable sources of financing

An overall strategy aiming to reduce the financial risks for investors should be developed. High initial costs need to be overcome with easier and improved access for project developers to be able to successfully provide finance. One measure that can mitigate this is creating awareness of SHP among local banking institutions or microfinance institutions to improve the risk assessment and provide conducive loan conditions.

(d) Facilitate access of the SHP industry to equipment and technology

The building or improvement of industries that serve as components of SHP will aid in the overall development of the SHP sector. In countries with insufficient local technology, access to imports can be aided through the establishment of concessionary duties and reduced import taxes.

(e) Provide reliable infrastructure

Developing robust grids with suitable capacity and coverage to accommodate new connections facilitates connecting SHP plants and is critical for attracting private investment. In countries with high distribution losses, investments in distribution systems should match those in the generation, to raise the overall efficiency of SHP projects. Establishing microgrids with SHP providing base-load power can also offer a short to medium-term—or even permanent—solution for electrifying remote and inaccessible communities.

(f) Improve local skills and expertise

By increasing local capacities in conducting feasibility studies, construction, operation and maintenance of SHP plants, the whole SHP sector can become more self-sufficient and long-lasting for countries.

(g) Strengthen international and regional cooperation

The promotion of SHP by international and regional institutions is essential for mainstreaming SHP as a positive renewable energy solution. On a more specific level, more information is needed on such topics as new SHP technologies, sustainable models for financing and ownership of SHP projects, the effectiveness of financial incentives for SHP development and the impact of the climate crisis on SHP. By developing South-South cooperation and triangular cooperation among developing countries, developed countries and international organizations, international and regional agencies can facilitate the transition of individual pilot SHP projects towards the successful implementation of full-scale SHP programmes.

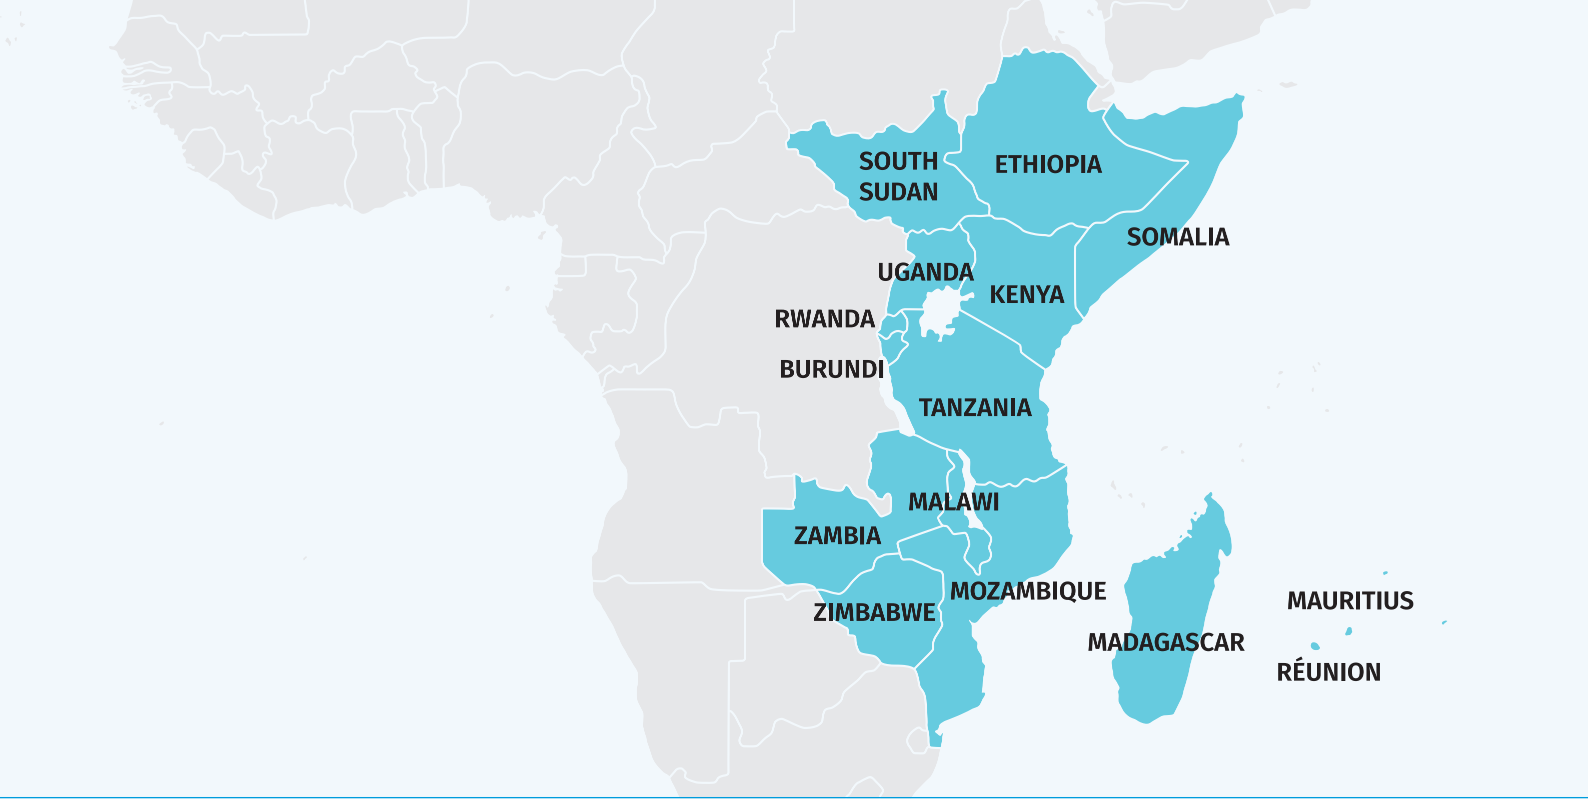
1. Africa



1.1. Eastern Africa

Countries: Burundi, Ethiopia, Kenya, Madagascar, Malawi, Mauritius, Mozambique, Réunion, Rwanda, Somalia, South Sudan, Tanzania, Uganda, Zambia, Zimbabwe

INTRODUCTION TO THE REGION

Countries comprising the Eastern Africa region are highly diverse in terms of geography, population dynamics and socio-economic conditions, with the regional electricity sector development reflecting this diversity. Access to electricity in the region ranges from 100 per cent in Mauritius to 7 per cent in South Sudan, which is also the lowest rate of electricity access in the world. Across other countries in Eastern Africa, access to electricity in the region averages below 50 per cent and displays significant disparities between urban and rural areas.

The main sources of electricity generation in Eastern Africa are thermal power and hydropower. Renewable energy sources other than hydropower are most widely represented by solar power, which exists in nearly all countries of the region but contributes a relatively small share of generated electricity. Kenya is the regional leader in geothermal power and, along with Ethiopia, employs considerable wind power capacities. Bioenergy from a variety of sources, including bagasse and bioethanol, is a widespread form of supplementary electricity generation in the region and accounts for a significant share of installed capacity in Réunion, Ethiopia, Malawi, Mozambique, Tanzania and Zimbabwe.

The role of hydropower in Eastern Africa is very significant, although installed and potential hydropower capacities vary widely by country. The regional leaders in hydropower generation are Ethiopia, Mozambique and Zambia. Hydropower is the largest single source of electricity generation in these three countries and additionally in Burundi, Malawi, Rwanda, Uganda and Zimbabwe. In Kenya, Madagascar, Mauritius, Réunion and Tanzania, hydropower is an important but supplementary source of electricity generation. There is no operational hydropower capacity in Somalia and South Sudan, although Somalia retains at least one major hydropower plant that is currently out of service.

An overview of the electricity sectors of the countries in the region is provided in Table 1.

Table 1. Overview of Eastern Africa

Country	*Total population (million people)*	*Electricity access, total (%)*	*Electricity access, rural (%)*	*Total installed capacity (MW)*	*Electricity generation (GWh/year)*	*Hydropower installed capacity (MW)*	*Hydropower generation (GWh/year)*

REGIONAL SMALL HYDROPOWER OVERVIEW

Countries in Eastern Africa adhere to different definitions of small hydropower (SHP). The up to 10 MW definition is the most common and has been adopted by Ethiopia, Mozambique, Réunion and Tanzania. Malawi and Rwanda use the up to 5 MW definition, while Uganda and Zambia adhere to the up to 20 MW definition. Finally, SHP is defined as up to 1 MW in Burundi, up to 3 MW in Kenya and up to 30 MW in Zimbabwe. No official definition of SHP exists in Madagascar, Mauritius, Somalia and South Sudan.

A comparison of installed and potential SHP capacities in the Eastern Africa region is provided in Table 2.

Table 2. **Small Hydropower Capacities by Country in Eastern Africa (MW)**

Country	*Local SHP definition*	*Installed capacity (local def.)*	*Potential capacity (local def.)*	*Installed capacity (≤10 MW)*	*Potential capacity (≤10 MW)*
Burundi	Up to 1 MW	2.2	30.5	17.4	61.0
Ethiopia	Up to 10 MW	12.9	1,500.0	12.9	1,500.0
Kenya	Up to 3 MW	N/A	N/A	66.3	3,000.0
Madagascar	N/A	N/A	N/A	37.0	836.0
Malawi	Up to 5 MW	4.7	150.0	12.9	150.0*
Mauritius	N/A	N/A	N/A	19.7	19.7
Mozambique	Up to 10 MW	4.8	1,000.0	4.8	1,000.0
Réunion	Up to 10 MW	10.6	16.6	10.6	16.6
Rwanda	Up to 5 MW	34.4	111.1	34.4*	111.1*

Country	Local SHP definition	Installed capacity (local def.)	Potential capacity (local def.)	Installed capacity (≤10 MW)	Potential capacity (≤10 MW)
Somalia	N/A	N/A	N/A	0.0	4.6
South Sudan	N/A	N/A	N/A	0.0	688.1
Tanzania	Up to 10 MW	30.5	480.0	30.5	480.0
Uganda	Up to 20 MW	186.0	400.0	107.9	214.1
Zambia	Up to 20 MW	N/A	N/A	18.7	62.0
Zimbabwe	Up to 30 MW	31.4	N/A	16.1	120.0
Total	**-**	**-**	**-**	**389.1**	**8,263.2**

Source: *WSHPDR 2022*[1]

Note: *Based on the local definition of SHP.

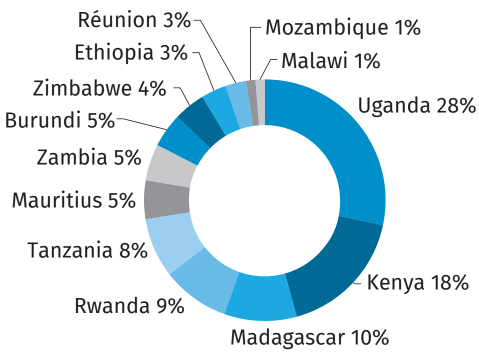
The total installed capacity of SHP up to 10 MW in Eastern Africa is at least 389.1 MW, while total potential capacity is estimated at 8,263.2 MW. Relative to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed capacity has increased by 41 per cent both due to ongoing SHP development in the region and access to better data on previously-existing plants. The potential capacity has increased by 21 per cent, largely as a result of a re-evaluation of SHP potentials in Madagascar and South Sudan.

SHP is a widespread source of electricity generation across much of Eastern Africa with the exception of Somalia and South Sudan and is commonly utilized for electrification of remote population centres as well as off-grid agro-industrial facilities including tea factories and multi-use facilities such as missions. SHP accounts for 23 per cent of all installed hydropower capacity in Madagascar, 33 per cent in Mauritius, 36 per cent in Rwanda and 39 per cent in Burundi, while hydropower capacities in other countries in the region are heavily dominated by large-scale plants.

Activity in the SHP sector in the region is uneven, with some countries actively pursuing SHP development and others prioritizing other renewable energy sources. In recent years, construction of new SHP plants has been most active in Uganda, Kenya, Madagascar, Rwanda and Zambia, while in other countries in the Eastern Africa region little new SHP development has taken place and changes in reported installed capacity are generally accounted for by more precise data on previously-existing SHP plants. Additionally, SHP development and planning in parts of the region is hampered by political and economic instability.

The national share of regional installed SHP capacity up to 10 MW by country is displayed in Figure 1, while the share of total national SHP potential utilized by the countries in the region is displayed in Figure 2.

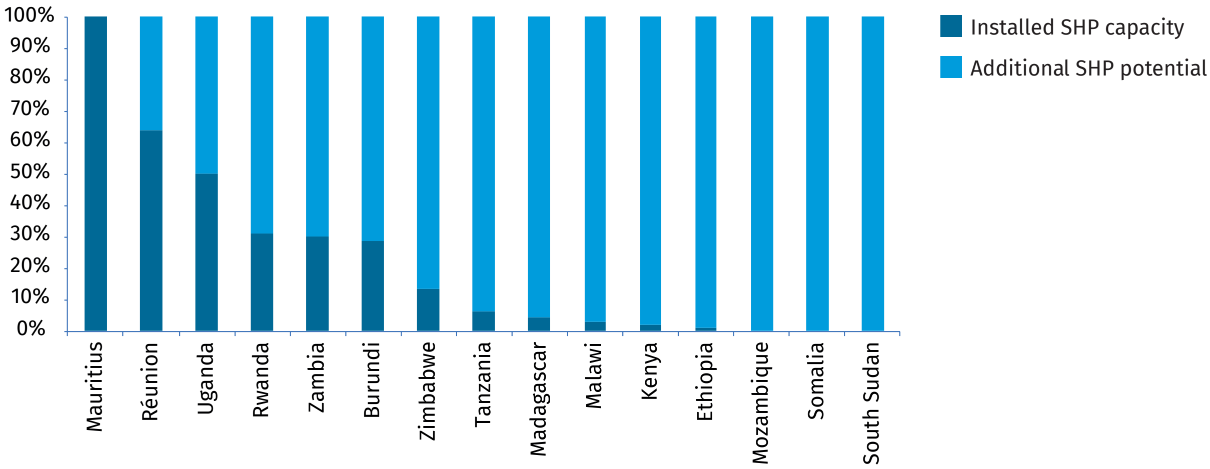
Figure 1. **Share of Regional Installed Capacity of Small Hydropower up to 10 MW by Country in Eastern Africa (%)**



Source: *WSHPDR 2022*[1]

Note: Somalia and South Sudan are not included due to lack of installed SHP capacity.

Figure 1. **Share of Regional Installed Capacity of Small Hydropower up to 10 MW by Country in Eastern Africa (%)**



Source: *WSHPDR 2022*[1]

The installed SHP capacity up to 1 MW in **Burundi** is 2.2 MW, while the estimated potential capacity is 30.5 MW, indicating that 7 per cent has been developed. For SHP up to 10 MW, installed and estimated potential capacities are 17.4 MW and 60 MW, respectively, indicating that 29 per cent has been developed. While no new SHP plants have been commissioned in recent years, two SHP projects with a cumulative capacity of 9.1 MW were in the planning stages as of 2021.

In **Ethiopia**, the installed capacity of SHP up to 10 MW is 12.9 MW, while potential capacity is estimated at 1,500 MW, indicating that less than 1 per cent has been developed. While Ethiopia is in the process of expanding its already considerable large hydropower capacity, the SHP sector in the country has seen little development in the last few years and there are no plans for the construction of any additional SHP plants in the near future.

The installed capacity for SHP up to 10 MW in **Kenya** is 66.3 MW, while potential capacity has been estimated at 3,000 MW, indicating that approximately 2 per cent has been developed. The country has actively pursued SHP development, with a large number of plants operated by the Kenya Tea Development Authority (KTDA) to support the operation of tea processing facilities. More than 260 potential SHP sites have been identified in studies carried out over the last decade, with the highest concentration of potential sites located in the Tana River basin. Many new SHP projects are either under construction or in the planning stages, with the KTDA continuing to play a key role in SHP development in the country.

The installed capacity of SHP up to 10 MW in **Madagascar** is 37 MW. The estimate of potential capacity, updated on the basis of a 2017 study, is 836 MW, suggesting that 4 per cent has been developed. SHP development in the country is actively on-going, with several new plants commissioned between 2019 and 2021 and three SHP projects under development as of 2021.

In **Malawi**, the installed capacity for SHP up to 5 MW is 4.7 MW, while potential capacity is estimated at 150 MW, indicating that 3 per cent has been developed. Recent activity in the SHP sector has included major reconstruction of existing SHP plants, with the total installed capacity of SHP up to 5 MW actually decreasing as several ageing plants were replaced by a newer SHP plant with an installed capacity of 8.25 MW in 2020. Consequently, the installed capacity for SHP up to 10 MW in the country reached 12.9 MW. Two additional ongoing SHP projects with a total capacity of 9.5 MW have passed the feasibility study stage.

Mauritius has an installed capacity of 19.69 MW for SHP up to 10 MW. No additional undeveloped potential has been identified, suggesting that the country's SHP potential is fully utilized. The most recently-constructed SHP plant was commissioned in 2019, but most of the country's SHP fleet is old and requires refurbishment. A government study has been launched to assess the existence of additional undeveloped potential.

The installed capacity for SHP up to 10 MW in **Mozambique** is 4.8 MW, while potential is estimated at 1,000 MW, indicating that less than 1 per cent has been developed. Little SHP development has taken place in the country over the last decade, as activity in the hydropower sector has been focused on large hydropower projects. The largest concentration of SHP plants in Mozambique is located in the central parts of the country and most existing plants have an installed capacity under 1 MW. Recent in-depth studies have identified hundreds of potential SHP sites across the country with a combined potential capacity of over 672 MW.

The installed capacity for SHP up to 10 MW in **Réunion** is 10.6 MW, with an additional 6 MW of untapped potential. The total estimated potential capacity in the country is thus 16.6 MW, of which 64 per cent has been developed. The last SHP plant in the country was commissioned in 2018. A number of additional SHP projects are in the planning stage, all with capacities under 1 MW.

In **Rwanda**, the installed capacity for SHP up to 5 MW is 34.4 MW, while the potential capacity is estimated at 111.1 MW, indicating that 31 per cent has been developed. The country has seen active SHP development in recent years, with several new plants commissioned between 2017 and 2020. Likewise, 10 additional plants are expected to become operational by 2024.

Somalia has no operational SHP capacity, although the existence of one previously operational SHP plant suggests a potential capacity of at least 4.6 MW if the plant were to be refurbished or rebuilt. The SHP sector in the country is stagnant, although plans to rehabilitate the existing SHP infrastructure in the country have been announced by the Government in a 2016 report.

South Sudan likewise has no operational SHP capacity. However, the potential capacity for SHP up to 10 MW is considerable, estimated at 688.1 MW in a 2018 study. There are no known plans for SHP development in the country on the national level and the country overall lacks a comprehensive renewable energy framework. Existing plans for renewable energy development focus on solar power projects and large hydropower.

The installed capacity for SHP up to 10 MW in **Tanzania** is 30.5 MW, while potential is estimated at 480 MW, indicating that approximately 6 per cent has been developed. The country has over 1,600 SHP plants, most of which are operated by faith-based groups for the provision of power to community facilities and health centres. Several SHP plants with capacities below 1 MW were commissioned between 2017 and 2019 and at least four different studies have identified hundreds of potential SHP sites across the country.

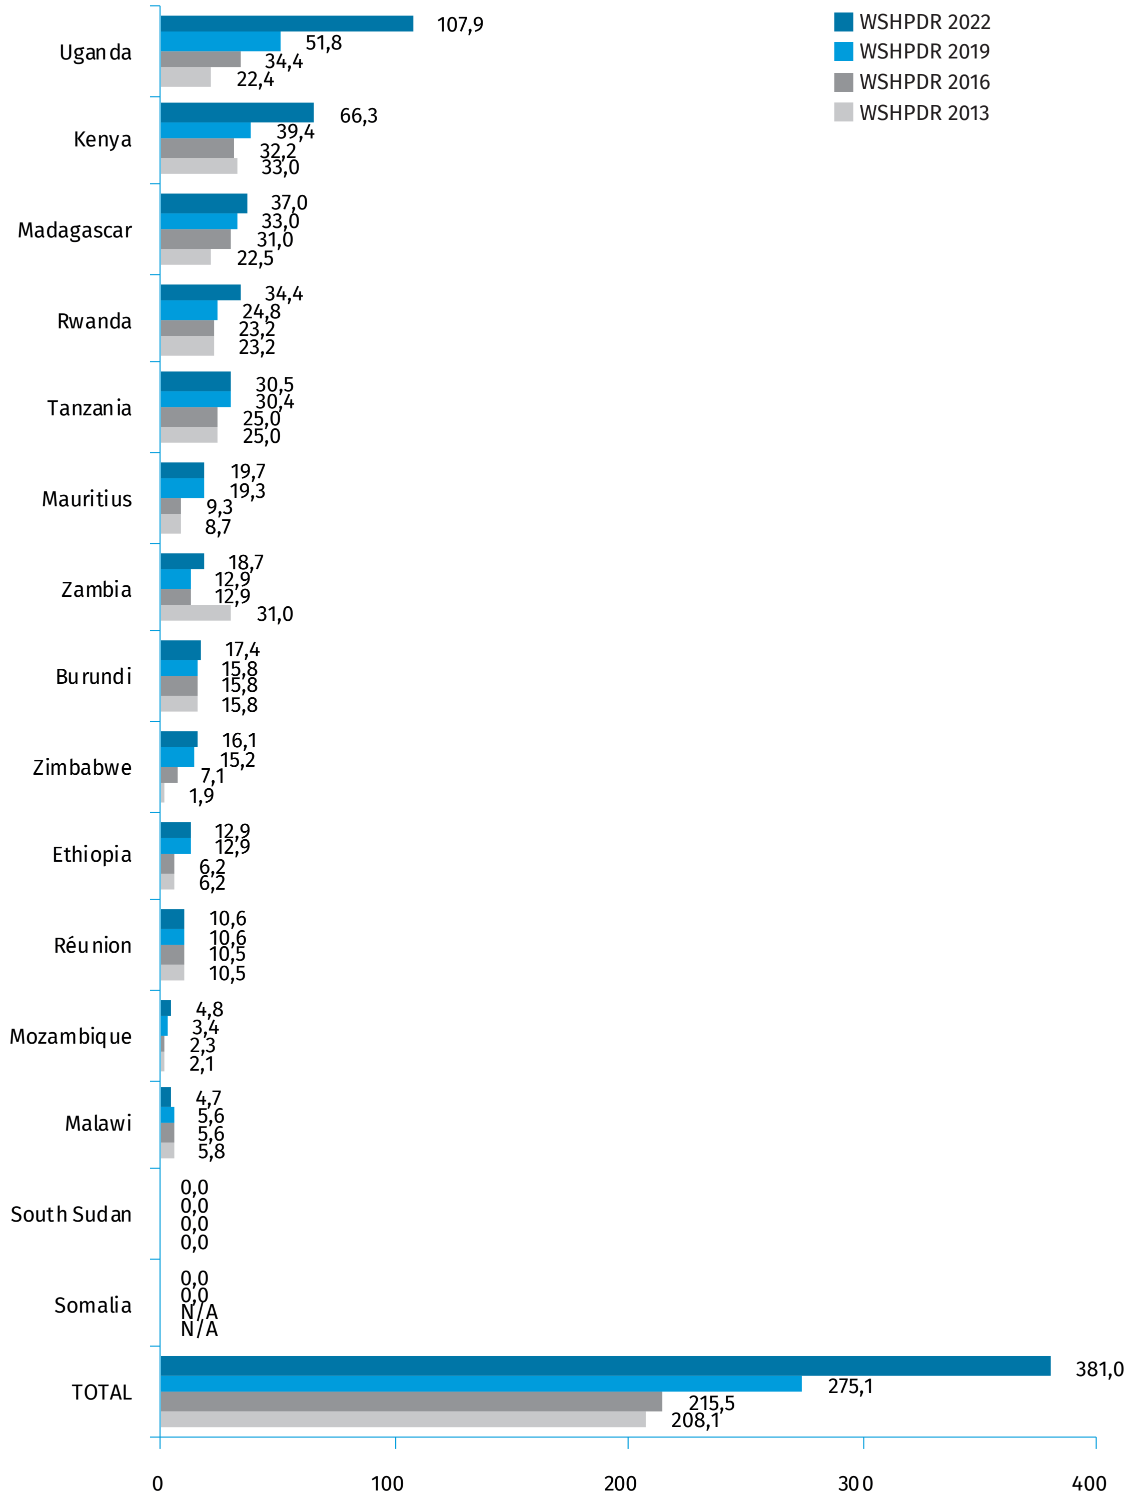
Uganda leads the Eastern Africa region in installed SHP capacity. The installed capacity of SHP up to 20 MW in the country is 186 MW, while estimated potential is 400 MW, indicating that 47 per cent has been developed. For SHP up to 10 MW, the installed capacity is 107.9 MW and estimated potential is 214.1, indicating that 50 per cent has been developed. SHP development in the country is very active, with over a dozen SHP plants up to 20 MW constructed between 2017 and 2022. Seventeen additional SHP projects were under construction as of 2022 and 20 potential SHP sites have been identified in various parts of the country.

The installed capacity of SHP up to 10 MW in **Zambia** is 18.7 MW, while the potential capacity is estimated at 62 MW, indicating that 30 per cent has been developed. The installed SHP capacity of the country has increased substantially due to the commissioning of two new SHP plants in 2020 with a combined capacity of 10.6 MW. In addition to new stream development, older SHP plants have either undergone refurbishment and capacity upgrades or have been decommissioned and replaced with new plants. Several SHP projects were in various stages of development as of 2020.

The installed capacity of SHP up to 10 MW in **Zimbabwe** is 16.1 MW, while the estimated potential capacity is 120 MW, indicating that approximately 12 per cent has been developed. For SHP up to 30 MW, the installed capacity is 31.4 MW, although no estimate of potential capacity is available. SHP plants in Zimbabwe are employed either as grid-connected facilities, which are operated by private companies, or as off-grid systems owned by communities and supported by non-governmental organizations (NGOs). One new SHP plant was commissioned in Zimbabwe in 2018 and several additional SHP projects are under construction.

Changes in the installed SHP capacities of countries in the region compared to the previous editions of the *WSHPDR* are displayed in Figure 3.

Figure 3. **Change in Installed Capacity of Small Hydropower from *WSHPDR 2013* to *WSHPDR 2022* by Country in Eastern Africa (MW)**



Source: *WSHPDR 2022,*[1] *WSHPDR 2013,*[2] *WSHPDR 2016,*[3] *WSHPDR 2019*[4]

Note: For SHP up to 10 MW with the exception of Malawi, where the local definition of SHP is used for consistent comparison with previous editions of the *WSHPDR*.

Climate Change and Small Hydropower

Almost half of the installed SHP capacity of Africa is located in Eastern Africa, with over 55 per cent of regional SHP capacity located in the Nile River basin. Climate change impacts on SHP in the region vary significantly depending on the models used. Projected variability in rainfall patterns and changes in temperature are likely to threaten water supply and storage, and pose a challenge to electricity generation in countries highly reliant on hydropower. A particular risk is a potential future decrease in wet season precipitation across the region. At the same time, expected increases in precipitation and runoff in certain parts of Eastern Africa can present an opportunity for SHP development. For example, some watersheds in Tanzania could see an increase in runoff of 160 per cent. Finally, climate change is expected to impact the reliability of estimates of hydropower potential in the region and the feasibility of previously identified sites. Consequently, older estimates of SHP potential in regional countries may no longer be accurate.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The development of SHP in **Burundi** is hampered by the lack of funds, local expertise in the SHP sector and limited hydrological data. At the same time, the country has a considerable untapped SHP capacity, with a range of potential sites already identified.

The main barrier to SHP development in **Ethiopia** is the Government's focus on large hydropower, which has resulted in a lack of funding for SHP as well as a lack of detailed and up-to-date information on potential SHP sites in the country. Ongoing political instability has been another factor holding back SHP projects. On the other hand, several recent government initiatives may be conducive to SHP development in the future, including a directive simplifying licensing for power generation on mini-grids and initiatives targeting rural electrification. The country's large untapped SHP potential suggests the country could considerably expand its overall generation capacity through SHP development.

Despite a robust and active SHP sector, SHP projects in **Kenya** face long lead times, high upfront costs and a lack of coordination between various government agencies responsible for SHP policy and oversight. More generally, climate change vulnerability and conflicts over land use present additional barriers to the implementation of SHP projects. However, SHP in Kenya also benefits from incentives including tax exemptions and feed-in tariffs (FITs), as well as from a well-established regulatory framework for public-private partnerships. Finally, the country's large undeveloped SHP potential is mapped in several recent studies.

Barriers to SHP development in **Madagascar** include a lack of funding opportunities, lack of local manufacturing capacity for turbines and risks induced by climate change. Enabling factors include the updated assessment of SHP potential in the country, which suggests the feasibility of SHP development on a greater scale than previously estimated, as well as the competitive per kWh cost of SHP in the country relative to other renewable energy sources.

SHP development in **Malawi** faces several significant obstacles including a lack of funding, lack of human capacity in the SHP sector and lack of awareness on the benefits of SHP among local communities. In addition, the SHP sector in the country is under pressure from environmental degradation, the vulnerability of old electrical infrastructure to extreme weather events, and vandalism of physical assets. At the same time, the demand for additional generation capacities is very high in Malawi due to low electricity access, and the existing untapped SHP potential in the country is well-studied. The Government provides certain tax exemptions for SHP projects and financing mechanisms for SHP are also available.

In **Mauritius**, the main obstacle for SHP development is the lack of identified undeveloped SHP potential. Government studies are underway to determine if undeveloped potential exists in the country, which could enable additional development in the SHP sector. Refurbishment of ageing SHP plants could present an additional opportunity for investment.

The development of SHP in **Mozambique** is hampered by the lack of a consolidated legal framework and the absence of an SHP-specific investment strategy, as well as the lack of locally-produced technology in the SHP sector. At the same time, the largely untapped and well-studied SHP potential in the country presents an important opportunity for meeting the electricity needs of remote and rural communities.

A major barrier to SHP development in **Réunion** is the island's isolated location, which significantly raises the cost of projects. Additional barriers unique to the island are its status as a World Heritage Site, volcanic activity and vulnerability to severe weather, all of which also contribute to raising the costs of SHP development. One promising direction for future SHP development in Réunion is the construction of SHP facilities on existing water supply infrastructure, which would minimize the impact of some of the aforementioned barriers.

Barriers to SHP development in **Rwanda** include the high cost of construction caused by difficult topography, geographic isolation and lack of local manufacturing capacity for SHP components, as well as unstable hydrological conditions. Enablers include the compatibility of SHP with micro-grids using other forms of renewable energy, suitable conditions for run-of-river plant construction and the Government's commitment to a climate-resilient model of development.

The main barrier to SHP development in **Somalia** is the ongoing political instability and fragmentation in the country, which severely complicates any development work. Additional barriers include the lack of financing from the private sector, local technical capacity in SHP and the limited regulation and oversight of the electricity sector. The main opportunity in the SHP sector in Somalia is the potential rehabilitation of the formerly operational 4.6 MW SHP plant.

The development of SHP in **South Sudan** is likewise hampered by political and economic instability, as well as by a focus on the development of fossil fuel-fired power plants, large hydropower and solar power. The main enabler for future development in the SHP sector is the country's large and fully undeveloped estimated SHP potential. SHP plants could be employed to at least partially address the problem of electricity access in the country, particularly in rural areas.

In **Tanzania**, barriers to SHP development include the lack of financing for projects as well as the problems with long-term financial sustainability of projects funded by NGOs, as the local customers are unable to bear the financial burden of power development and maintenance. SHP projects are also adversely impacted by issues with long-term planning and the lack of local technical expertise in the SHP sector. On the other hand, the country's large untapped SHP potential has been extensively studied and the country can lean on extensive experience in SHP project implementation. Additionally, Government policy is supportive of off-grid generation, and renewable energy sources including SHP plants are incentivized with standardized power purchase tariffs.

Despite a rapid pace of development, the SHP sector in **Uganda** is hampered by several obstacles, including deficiencies in the quality of the transmission and distribution network, limited local manufacturing capacity, a lengthy and bureaucratic process of land acquisition for projects and poor implementation of environmental oversight. Despite these issues, SHP development in the country is supported by a conducive regulatory environment and incentives for power generation from SHP, including several categories of FITs, in addition to other forms of government support and long-term planning, particularly with regard to using SHP to extend electricity access to rural communities.

Barriers to SHP development in **Zambia** are multi-faceted and include a lack of accurate hydrological data, lack of a comprehensive energy policy, issues with power transmission, financing and incentivization of investments through tariffs. The poor quality of the road network creates additional complications in accessing potential SHP sites. On the other hand, the country has a stable and growing market for electricity with steadily increasing demand, as well as an array of economic and fiscal incentives for SHP development including several categories of FITs, tax incentives, risk cost sharing and subsidies.

In **Zimbabwe**, barriers to SHP development include extreme weather conditions, lack of standard FITs and procurement methods, high cost of local financing coupled with lack of access to foreign financing opportunities and the lack of local manufacturing capacity for SHP equipment. The primary enablers of SHP development in the country are the substantial undeveloped SHP potential and the availability of net metering for SHP projects.

Burundi

Willy Ciza, Ministry of Hydraulics, Energy and Mines

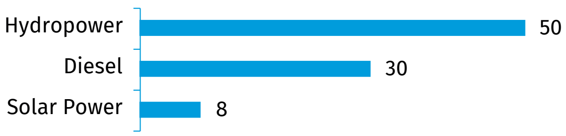
KEY FACTS

Population	12,255,429 (2021)[1]
Area	27,834 km^2 [2]
Topography	The terrain of Burundi is dominated by plateaus and mountains. Plains are only found along the Ruzizi River, north of Lake Tanganyika, forming the border with the Democratic Republic of the Congo. In the west of the country, mountain ranges run from north to south, culminating at Mount Heha, which reaches 2,670 metres above sea level.[2]
Climate	The climate is equatorial, with temperatures ranging according to altitude, from 12 °C at high altitudes in the western mountainous areas to 32 °C in the plains, near Lake Tanganyika and at the Ruzizi River Plain. The capital city of Bujumbura experiences an average annual temperature of 23 °C.[2]
Climate Change	The key climate change impacts experienced by Burundi include increased heavy rainfall, leading to floods and soil erosion; precipitation reduction and long periods of drought, resulting in reduced water resources; increased heat and more frequent extreme weather events. In 1991–2020 the mean temperature was 0.5 °C higher than in the 1971–2000 period and almost 1 °C higher than in 1951–1980. Conversely, mean precipitation reduced, decreasing by an average of 7 mm per decade over the 1951–2020 period.[3]
Rain Pattern	The wet season in Burundi lasts from October to April and the dry season from May to September. Annual precipitation varies by region, ranging from 800–1,000 mm in the north-east to 1,600–2,000 mm at higher elevations in the mountains.[4]
Hydrology	The four major rivers are the Kanyaru, Malagarasi, Rusizi and Ruvubu. The largest lakes are Tanganyika, Cohoha and Rweru.[5]

ELECTRICITY SECTOR OVERVIEW

In 2022, the total installed capacity of Burundi was approximately 88 MW, which consisted of approximately 50 MW of hydropower, 30 MW from a diesel-fired power plant and 7.5 MW from one solar power plant (Figure 1).[6,7,8,9] Additionally, Burundi imports 15.5 MW from the regional Ruzizi hydropower complex located on the border between the Democratic Republic of the Congo and Rwanda.

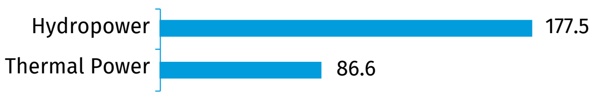
Figure 1. **Installed Electricity Capacity by Source in Burundi in 2022 (MW)**



Sources: Ciza,[6] Nsabimana,[7] Anadolu Agency,[8] REPP[9]

In 2020, electricity generation by the state-owned company Directorate for Production and Distribution of Water and Electricity (REGIDESO) amounted to 264 GWh, of which hydropower accounted for 67 per cent (Figure 2).[10] REGIDESO owns the majority of the electricity generation capacity in the country, however, besides its plants there are also plants owned by the Rural Electrification Agency (ABER) and independent power producers (IPPs). Total electricity generation in the country in 2020 including all producers amounted to 346.3 GWh, however, a breakdown by source for this total is not available.[11]

Figure 2. **Annual Electricity Generation by Source in Burundi in 2020 (GWh)**



Source: ISTEEBU[10]

Note: Includes only generation by REGIDESO.

The World Bank reports an almost 12 per cent national electricity access rate and less than 4 per cent in rural areas.[12,13] However, no studies to determine the electricity access rate in the country have been carried out and these values should be considered as indicative. Overall, electricity supply critically lags behind demand. The Government of Burundi has implemented the policies and regulations to improve the country's energy sector, with a particular focus on renewable energy sources. The goal is to develop the economy, reduce poverty and create more opportunities for income generation from the energy sector.

In order to improve electricity access, a number of projects are currently under development, including, the 49 MW Jiji-Murembwe, 20 MW Kaburantwa and 10.4 MW Mpanda hydropower plants.[7] The plants most recently added to the country's generation fleet include the 7.5 MW solar plant in Mubuga and the 15 MW Ruzibazi hydropower plant in the south of Bujumbura.[8,9] In rural areas, the Government has set up two projects, Soleil Nyakiriza and Umuco w'Iterambere, in order to increase the rate of access to electricity, mainly for public infrastructure (health centre and secondary school) and to create a market for solar equipment in Burundi.

The electricity transmission system in Burundi is made up of 750 kilometres of 110 kV high-voltage lines and 30 kV medium-voltage lines.[14] Due to its dilapidated state, the electricity network does not support the load that passes through it, which leads to blackouts and electricity shortages. Studies are being finalized to rehabilitate the electricity network, mainly in the city of Bujumbura.

The Government of Burundi has opened the country's energy sector to private actors through the liberalization of the renewable energy sector. Investors can participate in electricity production, transportation and distribution as well as carry out marketing activities for the electricity produced. REGIDESO manages the electricity transmission and distribution infrastructure throughout the country, therefore, it acts as the buyer for projects undertaken within the public-private partnership (PPP) framework. For isolated power plants, a legal framework is in place to facilitate customer connection and electricity sales.

Electricity tariffs in Burundi were established in 2017 and are uniform on the entire territory of the country with differentiation according to the customer type (Table 1).[15]

Table 1. **Electricity Tariffs in Burundi**

Type of consumption	*Tariff (FBU/kWh (USD/kWh))*	*Fixed charge (FBU/Month (USD/kWh))*
Households (0–50 kWh)	82 (0.047)	0 (0)
Households (51–150 kWh)	290 (0.166)	0 (0)
Households (≥151 kWh)	546 (0.312)	6,822 (3.898)
Commercial (0–100 kWh)	195 (0.112)	4,122 (2.355)
Commercial (101–250 kWh)	313 (0.179)	8,266 (4.723)
Commercial (≥251 kWh)	399 (0.228)	12,398 (7.085)
Administration	313 (0.179)	11,500 (6.571)

SMALL HYDROPOWER SECTOR OVERVIEW

Small hydropower (SHP) is defined in Burundi as hydropower plants with capacity of up to 1 MW.

According to the local definition, there are 16 SHP plants in the country with a combined installed capacity of 2.2 MW (Table 2) and an annual generation of 76 GWh.[6] The potential of SHP up to 1 MW is estimated at 30.5 MW.[16] Following the up to 10 MW definition of SHP, the installed capacity of Burundi is 17.39 MW, while the potential, as determined based on planned SHP projects, is 61 MW.[6,16] The changes in installed capacity compared to the *World Small Hydropower Development Report (WSHPDR) 2019* are based on more accurate estimates, whereas the potential estimates have remained unchanged (Figure 3). No new SHP projects have been launched since the previous edition of the report; however, a number of projects are planned as part of the country's efforts to advance the renewable energy sector, including the 300 kW Karonke plant and the 8.8 MW cascade at Dama.[4]

The total hydropower potential in the country has been estimated to be approximately 1,700 MW, of which approximately 300 MW is economically viable.[19] Table 3 shows a list of selected potential sites identified for SHP development in the country.

RENEWABLE ENERGY POLICY

The Government of Burundi aims to promote renewable energy as part of its efforts to protect the country's natural resources. This includes a range of planned hydropower, solar power, peat-fired and waste-to-power projects as well as exploration of the wind power and geothermal power potential in the country.[20] To support these efforts, the Government has prepared renewable energy legislation, which at the moment of writing of this chapter was under consideration. There are no feed-in tariffs in place.

As the majority of population uses wood as a source of energy for cooking, the Government of Burundi has planned a programme of planting trees across the country and calls the population to use other less polluting sources of energy, for example, ecological briquettes from biodegradable waste.

The following laws aiming to further liberalize the electricity sector have been implemented:

- Law No. 1/23 of 24 September 2008 defined tax benefits for investors;
- Law No. 1/177 of 19 October 2009 established the Investment Promotion Agency;
- Law No. 100/318 of 22 December 2011 established the ABER to develop and implement rural electrification projects and programmes;
- Law No. I/13 of 23 April 2015 aims to reorganize and liberalize the electricity sector;
- Electricity (Generation Services for Export and Electricity Importation) Regulations, 2016;
- Electricity Licensing (Generation Services for Own Use and Trade) Regulations, 2016;
- Electricity (Transmission, Distribution and Electricity Trade) Regulations, 2016.[16]

Licensing of SHP projects is overseen by the Regulatory Authority of Water and Energy Sectors (AREEN) and is a rather easy process. Each project is required to undertake an Environmental and Social Impact Assessment (ESIA).

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

The Government of Burundi is the main source of financing for SHP projects in the country, including through PPPs and loans.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

So far, only minor effects of the climate crisis on the hydropower sector have been recorded in the country. Electricity generation drops in the summer period, which should be taken into account in future SHP developments. As adaptation measures for the hydropower sector, the Government uses generation from thermal power and plants trees around hydropower plants.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The key barriers preventing SHP development in Burundi include:

- Lack of funds;
- Lack of local skills and expertise;
- Limited hydrological data.

At the same time a range of favourable conditions for SHP development exist:

- A very low electricity access rate and need for electricity sector development so that the country can develop economically, socially and financially;
- Significant improvements in the business environment in the country have been made;
- Policy focus on hydropower development;
- A range of suitable SHP sites have been identified.

Ethiopia

Zelalem Girma, Arba Minch University; and Davy Rutajoga, International Center on Small Hydro Power (ICSHP)

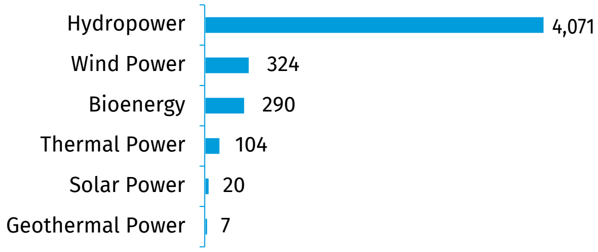
KEY FACTS

Population	114,963,583 (2020)[1]
Area	1,129,300 km^2[2]
Topography	Ethiopia has one of the most rugged topographies in Africa that can be categorized into five zones: the Eastern Highlands, the Western Highlands, the Eastern Lowlands, the Western Lowlands and the Rift Valley. The highest point in the country is the Ras Dejen (or Ras Dashen) mountain, peaking at 4,533 metres.[3]
Climate	Ethiopia is located in the tropical latitudes and thus experiences climatic conditions typical of tropical regions in its lowlands. The country's highlands, however, enjoy a temperate climate due to their elevation offsetting the desert-like conditions of the lowlands. This variety in topography translates into mean temperatures ranging from -15 °C in the highlands to over 25 °C in the lowlands.[4]
Climate Change	Ethiopia has been experiencing increasing temperatures and variabilities in rainfall patterns due to climate change. The average temperatures have been increasing, especially in the July-September period, by an average of approximately 1 °C since 1960, with an average increase rate of 0.25 °C per decade. The average number of hot nights and hot days has increased, while cold days have also been decreasing exponentially. The higher rates of warming have been observed to affect the central regions and highland areas more, with increased evapotranspiration and reduced soil moisture. There has also been observed a decrease in precipitation and an increase in volatility. The south-central region, for example, has seen a 20 per cent decrease in rainfall since 1960. This has all led to increased droughts and unpredictable rainfall patterns.[4]
Rain Pattern	Ethiopia experiences considerable variability in rainfall. The equatorial forests in the south and south-west receive high rainfall. Conversely, while the Afroalpine zone on the Bale and Simien Mountains as well as the eastern, north-eastern and south-eastern lowlands experience desert-like conditions. Ethiopia has three rainfall seasons: the rainiest season, or Kiremt, accounting for most of the rainfall between June and September; the Belg, which is a secondary wet season from February to May in the central and northern regions; and the Bega in the southern regions, which occurs from October to December. The mean annual rainfall is approximately 2,000 mm in the south-western highlands and approximately 300 mm in the south-eastern and north-eastern lowlands.[4]
Hydrology	Ethiopia has 9 major rivers and 12 big lakes, including Lake Tana, which is the source of the Blue Nile. There are three major drainage systems in Ethiopia: the Western drainage, which includes the Blue Nile (or the Abay River), the Baro Rivers and the Tekeze and flows towards the White Nile in South Sudan and Sudan; the Rift Valley internal drainage system, including the Awash River, Omo River and the Lakes Region; and the Shebele and Genale Rivers drainage system which flows southwards towards Somalia and the Indian Ocean.[3]

ELECTRICITY SECTOR OVERVIEW

The main sources of electricity in Ethiopia are hydropower, wind power, bioenergy and solar power, respectively accounting for 93.9 per cent, 5.8 per cent, 0.2 per cent and 0.1 per cent of total production, which amounted to 14,553 GWh in 2019. All electricity production in the country was from renewable sources, with hydropower alone amounting to 13,655 GWh in 2019 (Figure 1).[5]

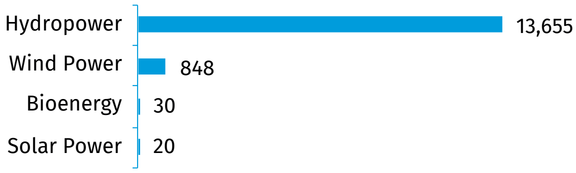
Figure 1. **Annual Electricity Generation by Source in Ethiopia in 2019 (GWh)**



Source: IRENA[5]

In 2020, the total installed electricity capacity in Ethiopia was 4,817 MW of which hydropower, wind power, bioenergy, solar power and geothermal power accounted for almost 85 per cent, less than 7 per cent, 6 per cent, 0.4 per cent and 0.3 per cent, respectively. Non-renewable thermal power capacity amounted to 104 MW (or 2.1 per cent) in 2020 (Figure 2).

Figure 2. **Installed Electricity Capacity by Source in Ethiopia in 2020 (MW)**



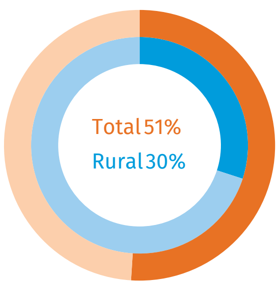
Source: IRENA[5]

Electricity in Ethiopia is regulated by the Ethiopia Electric Authority (EEA), while the Ethiopian Electric Utility (EEU) and the Ethiopian Electric Power (EEP) are responsible for generation, transmission and delivery. The latter was formed by Council of Ministers Regulation No. 302/2013.[6]

The EEA regulates tariffs for on-grid and off-grid electricity, with tariffs in Ethiopia being some of the lowest in Africa due to government incentives and a fixed cost of electricity. This tariff underwent an amendment in 2018, after which costs were ranging from 0.005 USD/kWh to 0.04 USD/kWh for residential consumers, and for industrial consumers from 0.03 USD/kWh to 0.02 USD/kWh.[7]

Electricity and the energy sector in general are a focal point of the Ten-Year Perspective Development Plan (2021–2030) of Ethiopia, also known as Vision 2030. Under Vision 2030, Ethiopia is projected to become a lower-middle income country and reach a 100 per cent electrification rate by 2025. The National Electrification Programme 2.0 (NEP 2.0) is the national strategy outlining the plan to achieve universal access to electricity through on- and off-grid solutions. Adopted in 2019, it is tied into Vision 2030 and highlights large-scale projects to double electricity production such as the Grand Ethiopian Renaissance Dam (GERD) and the 2,160 MW Koysha hydropower plant. The former, a large-scale hydropower project, is expected to be completed by 2023 but has already begun producing electricity and is expected to reach a production capacity of 6,450 MW, making it the largest hydropower plant in Africa.[8,9,10]

Figure 3. **Electrification Rate in Ethiopia in 2020 (%)**



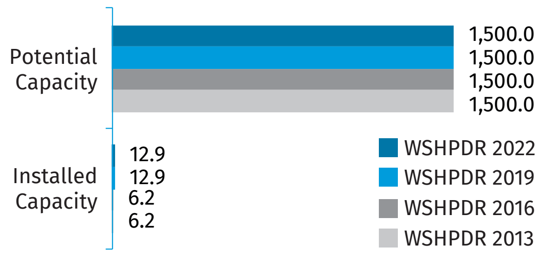
Source: World Bank[10]

The country's electrification rate was 51 per cent in 2020, with 30 per cent of the country's rural population having access to electricity (Figure 3). Electrification rates are expected to increase dramatically once the GERD is operating at full capacity.[11,12]

ALL HYDROPOWER SECTOR OVERVIEW

In Ethiopia, small hydropower (SHP) refers to plants with an installed capacity of up to 10 MW. The installed SHP capacity in 2018 was 12.89 MW and the SHP potential is estimated to be at least 1,500 MW, with most potential sites located in western and south-western Ethiopia.[13,17] The potential and installed capacity have not changed since the publication of the *World Small Hydropower Development Report (WSHPDR) 2019* as no new data have been made available (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Ethiopia (MW)**



Source: *WSHPDR 2013*,[14] *WSHPDR 2016*,[15] *WSHPDR 2019*,[16] MoST[17]

There is currently no reliable information on the number of SHP plants in operation in Ethiopia. In 2017, there were 28 operational SHP plants (Table 1).

RENEWABLE ENERGY POLICY

As part of the NEP, a climate-resilient green economy approach is essential to achieving Vision 2030, and renewable energy is stated as one of the four pillars of this green economy. To achieve the Vision 2030 target of universal electricity coverage fixed by the Government of Ethiopia, a focus is made on the expansion of renewable energy in both the on- and off-grid mode.[9]

One of the policies addressed in the NEP is the National Biogas Programme (NBP) launched in 2009 with the aim of providing biogas digesters to Ethiopian households. In the first phase of the project, over 14,000 rural households were serviced and 360,000 low-income households are targeted for the current phase II. Further efforts to improve clean energy access in low-income households in the country were manifested in the National Improved Cookstove Programme (NICP), a programme launched in 2010 with the aim of providing cleaner cooking technologies to divest from traditional biomass-based fuels (firewood, charcoal). Within the first five years of implementation of the programme, over 9 million improved cookstoves had been distributed in Ethiopia. Under the Rural Electrification Fund launched in 2003, more than 45,000 solar home systems have been provided to previously unelectrified communities in Ethiopia and over 200 technicians were trained in the operation and maintenance of solar home systems.[9]

In response to the growing demand for renewable energy via off-grid systems, the Government of Ethiopia partnered with the International Development Association (IDA) to launch the Market Development Credit Line (MDCL) as part of the Electricity Network Reinforcement and Expansion Project (ENREP). Through this credit line, imports of technologies and equipment for renewable energy projects are facilitated by the supply of retail loans to Ethiopian private sector enterprises and small and medium-sized enterprises for up to two years, at 12 per cent interest and with guaranteed access to forex. The credit line also enables wholesale loans to Ethiopian micro-financial institutions in the local currency for up to six years at 6 per cent interest. The Government of Ethiopia is also considering alternative financial institutions to allow consumers in remote areas to be able to pay for their solar tariffs as part of the NEP.[9]

The Government has also implemented feed-in tariffs (FITs) for solar and wind projects, depending on the scale and location of the project, of between 0.05 USD/kWh and 0.06 USD/kWh.[14]

As a way to promote SHP development, the Government of Ethiopia introduced the Ethiopian Rural Energy Development and Promotion Centre (EREDPC). The EREDPC is overseen by the Ministry of Water, Irrigation and Energy and is mandated to promote and provide financing for SHP projects in rural Ethiopia through a rural electrification fund. Feed-in tariffs (FITs) are also being considered for hydropower to encourage private sector participation.[13]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

SHP plants are regulated by the same legislation as larger hydropower projects. The main legislation and regulation documents in Ethiopia concerning hydropower projects are:

- Energy Proclamation No. 810/2013 (as amended by Proclamation No. 1058/2018);
- Energy Regulation No. 447/2019 (Energy Regulation), which supplements the Energy Proclamation. It regulates the consent and permit procedures for generation, transmission and distribution licenses, and provides guiding principles on tariffs;
- Investment Proclamation No. 1180/2020. This is the key piece of legislation that regulates investments in any sector, including energy;
- The Federal Water Resources Management Policy (1999).

BARRIERS AND ENABLERS TO SMALL HYDROPOWER DEVELOPMENT

The development of new SHP projects is hampered mainly by:

- The lack of available relevant information on the state and future of SHP in the country, which can discourage prospective investors;
- Although studies of hydropower potential are regularly conducted in the country, they often target larger-scale hydropower;

- Increasingly volatile political situation and conflicts affect SHP development as entire regions of the country are often out of access or too dangerous to be visited for potential site analysis. Many water resources are also found in these out-of-reach zones of conflict;
- The focus on large-scale hydropower projects to respond to the growing demand for electricity, such as the GERD project, is likely to eclipse the potential of SHP in solving those issues, particularly in remote and rural areas.
- Lack of expertise in manufacturing, installation and maintenance of equipment or parts for SHP plants;
- Expansion of irrigation projects in small hydrostreams may prevent hydropower development downstream.

Enablers for SHP development in Ethiopia include:

- Government support for renewable energy in general: this is an encouraging sign as future policies are likely to keep reflecting this engagement;
- Institutional support for hydropower development through encouraging policies that target small-scale renewable energy development, particularly in rural Ethiopia;
- Considerable water resources and SHP potential in Ethiopia;
- Increasing foreign investment and private sector involvement in small-scale off-grid reflects an increasing interest in renewable energy solutions to the electrification issues of the country;
- Establishment of the EREDPC with a mandate to promote renewable energy technologies for rural electrification. Under the EREDPC, soft loans with low interest rates are available to private power producers;
- The mini-grid directive launched in 2020 simplifies the process of obtaining licences for electricity generation, distribution and sale as well as tariff setting.

Kenya

Sarah Acholla Kwach, Kenya Industrial Research and Development Institute (KIRDI)

KEY FACTS

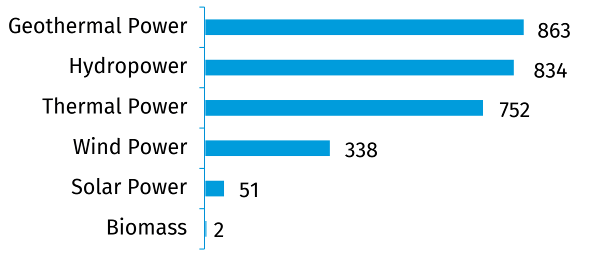
Population	53,771,300 (2020)[1]
Area	580,370 km[2] [2]
Topography	Kenya is located across the equator and is characterized by a diverse topography varying across its 47 counties.[3] Its Indian Ocean coastline contains swamps of the East African mangroves. Inland are broad plains and numerous hills. Central and western Kenya is characterized by the Rift Valley, home to the country's highest mountain and the second highest mountain in Africa, Mount Kenya, with an altitude of 5,199 metres above sea level. The landscape of Kenya includes deserts, such as the Chalbi, as well as glaciated mountain ranges.[2]
Climate	The climate of Kenya ranges from tropical in the southern, western and central regions to arid and semi-arid in the north and north-east.[4] Meanwhile, the country's central highlands have an equatorial climate.[5] Temperatures average 27 °C in the coastal areas, 19 °C in the capital, Nairobi, and 13 °C in the mountains.[6]
Climate Change	Climate change in Kenya has been well-documented, with both minimum and maximum daily temperatures on the rise since the early 1960s. Between 1960 and 2006, the minimum temperature has increased by 0.7-2.0 °C and the maximum by 0.2-1.3 °C.[7] Regionally, western parts of the country have seen the most significant temperature rise, with surface temperatures around Nairobi having risen by more than 2.5 °C since the 1960s. On the contrary, coastal areas have experienced more moderate warming trends. Projections of climate change for countries in the Eastern Africa region, including Kenya, forecast an increase in mean annual temperatures of 2.2 °C by 2065 and 4.0 °C by 2100 under a high-emissions scenario.[8]
Rain Pattern	The two rainy periods in Kenya are set apart by dry periods and referred to as the "long rains", from March to May, and the "short rains", from October to December. These have extensive implications for the country's agricultural system, with different crops being grown during each rainy period. The average annual rainfall is 630 mm, with a variation from less than 200 mm in northern Kenya to over 1,800 mm on the slopes of Mount Kenya.[2,9]
Hydrology	The drainage system of Kenya consists of five major basins: Lake Victoria, Rift Valley, Athi and the coastal area, Tana and Ewaso-Nyiro/North-Eastern. The two largest perennial rivers are the Tana (724 km) and the Athi-Galana-Sabaki (390 km). Both empty into the Indian Ocean.[10]

ELECTRICITY SECTOR OVERVIEW

The electricity sector of Kenya is characterized by a diversified energy mix and a high degree of reliance on renewable energy sources (RES). Petroleum products still form a major component of the national energy consumption, including for electricity generation, and demand for them continues to increase by approximately 10 per cent annually. However, Kenya is also endowed with an abundant RES potential, varying in type across geographic areas. The solar power potential is high across the country, while potential for biomass and hydropower is plentiful in the wet, forested central and southern regions. The wind power potential is highest in the north-west and parts of the Great Rift Valley, which also contains much of the country's geothermal energy resources.[11,12,13,14]

The installed generation capacity of Kenya has been increasing in recent years, and rose from approximately 2,819 MW in 2019 to 2,840 MW in 2020; however, the effective and contracted capacity in 2020 reached only 2,708 MW, in part due to the impact of the COVID-19 pandemic on the country's electricity sector.[14,15,16] Geothermal power was the single largest contributor of installed capacity in 2020 at 863 MW (30 per cent). Meanwhile, hydropower contributed 834 MW (29 per cent), thermal power 752 MW (26 per cent), wind power 338 MW (12 per cent), solar power 51 MW (2 per cent), and biomass 2 MW (less than 1 per cent) (Figure 1).[14] The geothermal power capacity expanded substantially in 2019 with the addition of the 165-MW Olkaria V plant, cementing the position of Kenya as one of the world leaders in geothermal power.[16,17] Given the additional importance of hydropower in the country's energy mix, the geothermal power capacity of Kenya is crucial in ensuring the security of electricity supply in periods of drought, with traditional thermal power deployed in a supplementary capacity. By the end of 2021, the installed capacity of traditional thermal power is expected to decrease to 622 MW, reflecting the country's ongoing transition to RES.[14]

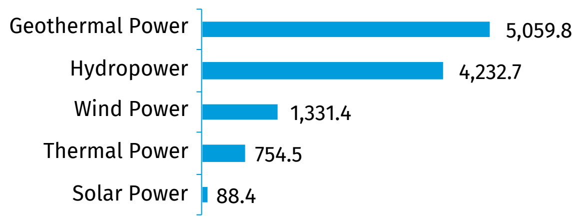
Figure 1. **Installed Electricity Capacity by Source in Kenya in 2020 (MW)**



Source: Government of Kenya[14]

In 2020, annual electricity generation in Kenya equalled 11,466.9 GWh, increasing slightly from 11,408.6 GWh in 2019. Of this total, 93 per cent of electricity was generated from renewable sources; geothermal power provided 5,059.8 GWh (44 per cent), hydropower 4,232.7 GWh (37 per cent), wind power provided 1,331.4 GWh (12 per cent), and solar power 88.4 GWh (1 per cent). Generation of electricity by thermal power, the only non-renewable source, accounted for 754.5 GWh (7 per cent) (Figure 2).[16]

Figure 2. **Annual Electricity Generation by Source in Kenya in 2020 (GWh)**



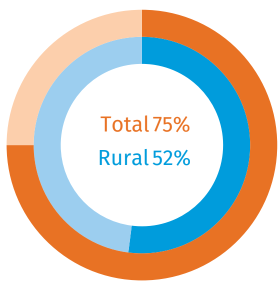
Source: KNBS[16]

In 2019, wind power generation experienced a more than four-fold increase relative to the previous year and reached 1,562.7 GWh, due to the full operationalization of the 310 MW Lake Turkana wind power plant, while solar power generation increased by nearly seven times relative to 2018 due to the commissioning of the Garissa power plant. However, in 2020 generation from both energy sources decreased slightly. In 2019, imports of electricity reached 212.0 GWh, but decreased to 136.7 GWh in 2020.[16,18]

In 2020, the total electricity supply decreased to 11,603.6 GWh from 11,620.7 GWh in 2019, with domestic demand falling to 8,796.4 GWh from 8,854.0 GWh over the same period. Transmission and distribution losses amounted to 2,790.7 GWh in 2020, accounting for 24 per cent of the total electricity supply.[16] Prior to 2020, Kenya had been experiencing an upward trend in electricity demand. The rise in demand has been associated with the increased number of consumers connected to the grid and the Government's efforts to attain universal access to electricity by 2022, as laid out in the Kenya National Electrification Strategy 2018–2022.[17] However, the economic slowdown induced by the COVID-19 pandemic led to a decrease in electricity demand of up to 8 per cent, with a system peak demand of 1,926 MW in February 2020 dropping to 1,465 MW in April 2020.[19] Further expansion of generating capacity to meet the rising demand is targeted at geothermal power, as part of a push to eliminate generation from fossil fuels.[20]

In 2018, access to electricity in Kenya stood at 75 per cent, with 52 per cent in rural areas (Figure 3).[21,22] Nationwide, almost 54 per cent were connected to the national grid and another 22 per cent were using off-grid solutions as their main source of electricity.[21] By 2020, overall access to electricity increased to 77 per cent, establishing Kenya as a regional leader in electricity access. The number of consumers connected to the national grid has grown rapidly in recent years, from 3,611,904 customers in 2015 to 7,576,145 in 2020, with an average annual increase of approximately 19 per cent. During the 2019/2020 reporting year alone, over 400,000 new customers were connected to the national grid. Rural connections reached 1,502,943 customers in 2020, accounting for approximately 20 per cent of all connections.[14,15] These results were achieved through a number of interventions by the Government of Kenya in collaboration with development partners, including the Last Mile Connectivity Programme (LMCP), electrification of all public primary schools, the Global Partnership on Output-Based Aid (GPOBA), the Rural Electrification Programme (REP), the Kenya Off-Grid Solar Access Project (KOSAP), the Slum Electrification Project (SEP), the Lifeline Tariff and the Energy and Cash Plus Initiative.[17]

Figure 3. **Electrification Rate in Kenya in 2018 (%)**



Source: The World Bank[21,22]

Despite the accelerating growth of the electrification rate, nearly 25 percent of the population still lack access to electricity.[15] Obstacles to full electrification include high connection charges, high costs of supplying electricity to rural areas, lack of incentives for private investment, inappropriate technical standards, general lack of capacity, administrative barriers and demands for excessive compensation for the issuing of development licences.

The key institutions in the energy sector of Kenya include the following:

- Ministry of Energy and Petroleum (MOEP), the lead Government institution in charge of making and articulating energy policies as well as granting and revoking generation and distribution licences upon the recommendation of the Energy and Petroleum Regulatory Authority (EPRA);

- Energy Tribunal, an independent legal entity that arbitrates disputes between parties in the energy sector;
- Energy and Petroleum Regulatory Authority (EPRA), previously the Energy Regulatory Commission (ERC), the independent regulator established under the Energy Act, 2019. EPRA's mandate includes licensing, technical and economic regulation, enforcement and compliance and handling of complaints and dispute regulation;
- Kenya Power and Lighting Company (KPLC, also Kenya Power), a public company that transmits, distributes and retails electricity to customers in the country;
- Kenya Electricity Generating Company (KenGen), a state-owned company that owns approximately 72 per cent of the country's installed capacity and is responsible for developing new public sector generation facilities to meet increased demand;
- Rural Electrification and Renewable Energy Corporation (REREC), mandated by the Energy Act, 2019 to be the lead agency for the development of renewable energy resources other than geothermal power and large hydropower, in addition to its previous mandate of rural electrification;
- Geothermal Development Company (GDC), a wholly state-owned Special Purpose Vehicle that undertakes surface exploration of geothermal fields, explorations, appraisals, drilling, steam production and entering into steam sales agreements with investors in geothermal electricity generation;
- Electricity Transmission Company (KETRACO), a wholly state-owned company responsible for the development of the national transmission grid network and for the facilitation of regional power trade through the transmission network;
- Independent Power Producers (IPPs), involved in generation either on a large scale or in renewable energy projects under the feed-in-tariff policy;
- Nuclear Power and Energy Agency (NPEA), formerly Kenya Nuclear Electricity Board (KNEB), a state-owned corporation established under the Energy Act, 2019 and charged with the responsibility of promoting and implementing the country's Nuclear Power Programme as well as carrying out research and development for the nuclear energy sector. To date, no nuclear plants have been built in Kenya;
- Kenya Renewable Energy Association (KEREA), an independent non-profit association dedicated to facilitating the growth and development of renewable energy enterprises in the country;
- Private distribution companies are proposed under the Energy Act, 2019 with the intention of enhancing competition in the distribution sector and thereby improving efficiency. It is envisaged that future power distribution will involve the purchase of bulk power from power generating companies. With KETRACO facilitating the transmission, generating companies will be able to sell power directly to consumers;
- County governments, which, under the Energy Act, 2019, are required to prepare county energy plans for the Cabinet Secretary. Some counties provide supplementary funding for rural electrification;
- Independent entities that act as arbiters in disputes between parties in the energy sector;
- Mini-grids, supplying electricity to a localized group of customers not covered by the national power grid as approved by EPRA.

Over the last years, the Government of Kenya has accelerated its efforts in upgrading the existing transmission and distribution networks and building new ones for effective power evacuation. The national grid network is composed of 400 kV, 220 kV and 132 kV transmission systems, while the distribution network includes 66 kV, 33 kV and 415/240 V systems.[15] The total length of the transmission and distribution network increased to 243,207 kilometres for all voltage levels in 2019/2020, compared to 59,322 kilometres in 2014/2015, with the length of the transmission network alone at 7,174 kilometres.[14] The expansion of the network has been spearheaded by KETRACO. As of the moment of writing of this chapter, KETRACO was in the process of constructing approximately 4,500 kilometres of new lines as well as connecting the power systems of Kenya and Ethiopia through the construction of a 1,045-kilometre 500 kV high voltage direct current (HVDC) transmission line and 2,000 MW HVDC converter substations at both ends of the line.[23,24] The Kenya-Ethiopia electricity interconnection will represent the longest transmission line in Eastern and Middle Africa, as well as the first direct current line in Kenya having 500 kV high-voltage direct current.[25] The entire national interconnected electricity distribution network is operated by KPLC.

EPRA sets, reviews and adjusts electricity tariffs and tariff structures in line with key policy objectives.[21.] The set tariffs must be approved by the regulator before enforcement. Retail electricity tariffs vary according to the customer category (Table 1).

Table 1. **Electricity Tariffs in Kenya for 2018/2019**

Consumer category	*Consumption limit (kWh/month)*	*Electricity charge (KSH/kWh (USD/kWh))*	*Demand charge (KSH/kVA (USD/kVA))*
Domestic-Lifeline (240 V)	< 100	10.0 (0.09)	-
Domestic-Ordinary (240 V)	> 100	15.8 (0.14)	-
Small Commercial 1 (240 V)	Up to 100	10.0 (0.09)	-
Small Commercial 2 (240 V)	101–15,000	15.6 (0.14)	-
Commercial/Industrial (415 V)	> 15,000	12.0 (0.11)	800 (7.28)
Commercial/Industrial (11 kV)	No limit	10.9 (0.10)	520 (4.73)
Commercial/Industrial (33 kV)	No limit	10.5 (0.10)	270 (2.46)
Commercial/Industrial (66 kV)	No limit	10.3 (0.09)	220 (2.00)
Commercial/Industrial (132 kV)	No limit	10.1 (0.09)	220 (2.00)
Street lighting	No limit	7.5 (0.07)	-

SMALL HYDROPOWER SECTOR OVERVIEW

The definition of small hydropower (SHP) in Kenya generally includes hydropower plants with an installed capacity of up to 3 MW (Table 2), but some government sources define SHP as plants of up to 10 MW.[27,28,29] For the purposes of this chapter, the up to 10 MW definition will be used.

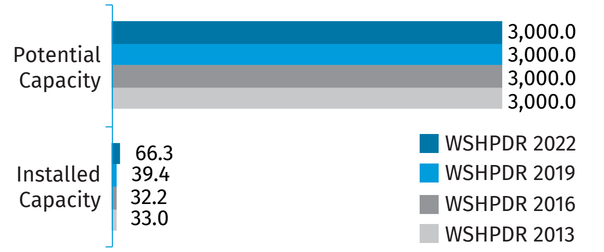
Table 2. **Definitions of Small Hydropower in Kenya**

Category	*Capacity range (kW)*
Pico	< 5
Micro	5–100
Mini	100–1,000
Small	1,000–3,000

Source: MOEP,[27] Ngure[28]

As of 2019, total installed capacity of SHP up to 10 MW in Kenya stood at 66.26 MW, including 26.99 MW operated by KenGen and 39.27 MW by private companies and rural communities.[14,18,30,31,32] Undeveloped potential capacity for SHP up to 10 MW is estimated at 3,000 MW.[29,33] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, installed capacity increased by approximately 68 per cent due to up-to-date information on recently commissioned plants becoming available. Potential capacity has remained the same as no new country-wide studies of SHP potential have been conducted since 2004 (Figure 4).[34]

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Kenya (MW)**



Source: Government of Kenya,[14] KPLC,[18] MOEP,[29] The World Bank,[30] Vogeler et al.,[31] EPRA,[32] *WSHPDR 2019*,[34] *WSHPDR 2013*,[35] *WSHPDR 2016*[36]

SHP development in Kenya accelerated following the introduction of the feed-in-tariff (FIT) policy in 2008, with the majority of new SHP plants constructed by the Kenya Tea Development Authority (KTDA). The plants are expected to significantly reduce energy costs of operation for KTDA tea factories as well as generate surplus electricity, which will be sold to the national grid.[31] A list of the 20 most recently commissioned SHP plants is displayed in Table 3.

Various studies conducted in Kenya over the past 10 years have identified many prospective sites for SHP development.[14,37,38] More than 260 individual potential hydropower sites have been identified, with the largest number found in the Tana River drainage basin, an area with a high population density and energy demand.[39] Both existing and prospective SHP plants in Kenya are often designed as stand-alone electricity supply facilities for agro-industrial establishments, in particular tea factories. A survey of 72 tea factories in Kenya indicated that 80 per cent are located 3–15 kilometres away from a potential hydropower site, although no detailed assessments of potential have been carried out. The KTDA can be expected to continue playing a major role in the development of SHP in the country, having committed itself to an array of SHP projects to be commissioned throughout the 2020s.[14] Table 4 displays several SHP projects currently under construction.

Table 4. **List of Selected Ongoing and Planned Small Hydropower Projects**

Name	*Location*	*Capacity (MW)*	*Developer*	*Planned Launch Year*
Kianthumbi	Meru	0.51	Hydro Project Service Peters Ltd.	2021

RENEWABLE ENERGY POLICY

The Energy Act, 2019 introduced various reforms to the energy sector of Kenya, aligning the sector with the Constitution of 2010 regarding the functions of the national and county governments.[40] Notably, through the introduction of the RES FIT system, the Act developed on the FIT policy introduced by MOEP in 2008 and reviewed in 2010, 2012 and 2021. The 2021 FIT Policy is a revision of the 2012 FIT Policy, with substantial changes introduced to the process of RES project development in Kenya to better align the Policy with the Energy Act, 2019 and other recent developments in the Kenyan energy sector. The FIT policy has been supplemented by the Renewable Energy Auction Policy (REAP) of 2021; FITs now apply to RES power plants not exceeding 20 MW and relying on biomass, biogas or small hydropower, while energy auctions have replaced FITs for solar and wind power and for all RES plants above 20 MW.[42] The current FITs for RES are listed in Table 5.

Table 5. **Feed-in Tariffs for Renewable Energy Projects in Kenya as of 2021**

Plant type	*Installed capacity (MW)*	*Standard FIT (USD/kWh)*	*Scalable portion of the tariff*
Hydropower	0.5	0.090	8%
	10	0.082	
Biomass	0.5 - 10	0.095	15%
Biogas	0.2 - 10	0.095	15%

Source: Ministry of Energy[43]

Note: For values between 0.5 MW and 10 MW, interpolation shall be applied to determine the tariff for hydropower.

The Energy Act, 2019 was adopted to consolidate the laws relating to energy and the promotion of RES, replacing the previously adopted Energy Act of 2006, Kenya Nuclear Electricity Board Order of 2013 and the Geothermal Resources Act of 1982. The new Act gave greater recognition to non-traditional energy sources, including RES and nuclear energy.[44] Additional legislation important for the RES sector includes:

- Sessional Paper No.4 of 2004, which cemented the process of liberalizing the energy sector started in the 1990s;
- the Electricity Licensing Regulations of 2012, which detail the permit and licensing requirements that are applied to any individual or entities undertaking or planning to engage in electricity generation, transmission, distribution or retail supply business;
- the VAT Act (2013) and the Amended VAT Act (2014), which exempt investors in RES from value-added tax and import duties on temporary and permanent materials and equipment required for RES projects;
- the Public-Private Partnerships Act of 2013, which provides for the participation of the private sector in the financing, construction, development, operation and maintenance of public infrastructure and development projects; and
- the Public Procurement and Asset Disposal Regulations of 2020, which seek to harmonize and operationalize public procurement procedures.[29,45]
- Renewable Energy Auction Policy (REAP) 2021, the primary objective of which is to procure renewable energy capacity in line with the LCPDP and the Integrated National Energy Plan (INEP) at competitive prices through the establishment of energy auctions.[42]

In additional to regulatory legislation, promotion of RES development in Kenya is realized through the following strategies and plans:

- The long-term development strategy of Kenya, Vision 2030, targets energy access as a key enabler for achieving its development targets, including projected increases in population, which are in turn expected to lead to a rise in electricity demand. According to the Least Cost Power Development Plan (2011–2031), the demand for electricity in Kenya is projected to grow to 15,065 MW by 2030;

- Sustainable Energy for All (SE4ALL) Action Agenda, which outlines how the country will achieve universal access to modern energy services, increase the rate of energy efficiency and increase the share of RES in the energy mix to 80 percent by 2030;
- The Kenya Electricity Sector Investment Prospectus 2018–2022, which outlines investment and financing opportunities in geothermal power development, power generation, electricity transmission and distribution, off-grid electrification and energy efficiency;
- The Investment Plan for Scaling-Up Renewable Energy (SREP), currently under implementation, supports the development of hybrid mini-grid systems based on RES for electrification in rural areas where grid extension is unlikely to be viable in the short and medium term.
- The Least Cost Power Development Plan (LCPDP) 2021 – 2030, which highlights the Government's intention to prioritize the development of geothermal, wind and solar energy plants as well as solar-fed mini-grids for rural electrification.[14]

The available incentives for RES development in Kenya include:
- Exemption from stamp duty for registration of companies;
- Exemption from stamp duty for instruments executed in transactions relating to loans from foreign sources for the purposes of investing in the energy sector;
- Investment deductions at the rate of 100 per cent for power generating plants and equipment, including the building housing the power generating plant and plants operating within Export Processing Zones; and at 150 per cent for plants located outside Nairobi, Mombasa and Kisumu;
- Insurance cover by the Multilateral Insurance Guarantee Agency (MIGA);
- Development of Public Private Partnerships by the Government in line with the Public Private Partnership Act No. 15 of 2013;
- Letters of support issued by the Government to both project companies and their financiers to enable project implementation;
- Kenya has no restrictions on converting or transferring investment funds;
- Foreign Investment Protection Act, Chapter 518, which guarantees capital repatriation and remittance of dividends and interest to foreign investors.

Licences and permits required for operating a power plant in Kenya include a generation licence and a distribution licence, both issued by MOEP; water rights (in the case of hydropower), obtained from the Ministry of Water Resources; and an Environmental Impact Assessment issued by the National Environmental Management Authority of the Ministry of the Environment. In case of sale of power to the grid, additional requirements include a power purchase agreement and adherence to generation and distribution standards.[46] Finally, approval of development permissions and building plans by the relevant county government and registration of the project site as a workplace with the Director of Occupational Safety and Health under the Occupational Safety and Health Act, 2007.

COST OF SMALL HYDROPOWER DEVELOPMENT

The cost of SHP construction in Kenya varies considerably based on location and the difficulty of preparing a site for construction, as well as other factors including the local economy and tax regime.[38] It is generally considered that the location and site preparation determine approximately 75 per cent of project costs, against only 25 per cent for the equipment.[47] The investment cost of an SHP plant in Kenya ranges anywhere from 1,000 to 20,000 USD/kW.[38] Maintenance costs of SHP plants in Kenya are relatively small in comparison to other technologies such as diesel generators. The initial investment cost as well as negative impacts on the environment can be greatly reduced by utilizing already existing impoundments and weirs.[38]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

Financing models utilized by developers in Kenya involve a combination of several approaches including community finance, public funding, equity investment, grants and loans from local financing institutions. For instance, in 2015, KTDA signed a KSH 5.5 billion (USD 50 million) loan agreement with the International Finance Corporation (IFC), in partnership with the Global Agriculture and Food Security Program (GAFSP), the French Development Finance Institution (Proparco) and the Netherlands Development Finance Company (FMO) to fund the construction of seven SHP projects across tea growing regions.[48]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT.

The hydropower sector of Kenya as a whole is vulnerable to climate change, creating broad implications for the entire economy due to the relative weight of hydropower in the country's energy mix.[49] Reduced rainfall in recent years has already made hydropower production increasingly unreliable, forcing the Government of Kenya to introduce new policies and strategies that place a greater emphasis on promoting other RES.[50] Furthermore, climate change is putting additional pressure on traditional fuels including firewood and charcoal, access to which is becoming increasingly restricted as forest cover has receded.[51] SHP projects can expect to face resistance if they are perceived as further limiting access to these resources.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Some of the main obstacles to the development of RES, and SHP specifically, in Kenya include the following:

- Relatively long lead times for RES projects (from five to seven years);
- High upfront investment and capital costs, including the cost of ancillary infrastructure due to long distances to existing load centres;
- Political risks and conflicts relating to land use;
- Inadequate expertise and technical capacity in the RES sector as well as limited local capacity to produce RES materials and equipment;
- Lack of coordination between government agencies in policy implementation and promotion of RES projects, excessive licensing requirements as well as weak enforcement of standards and regulations;
- Vulnerability to climate change;
- Lack of awareness of the economic benefits of RES.

Additional barriers, specifically pertaining to the implementation of the FIT policy, include the following:

- Insufficient data and analytical tools to accurately formulate the tariff rates for different technologies;
- Lack of awareness of FITs among potential investors;
- No clear guidelines on power purchase agreement negotiations;
- Preference for certain RES technologies over others.

Enablers for SHP development include:

- High potential capacity of SHP, little of which has been realized so far;
- Incentives, including FIT and exemptions from certain taxes and duties on RES; and
- Favourable climate for private investors, which includes a robust public-private partnership framework.

Madagascar

Joelinet Vanomaro, Technical Director of Rural Electrification Agency (ADER)

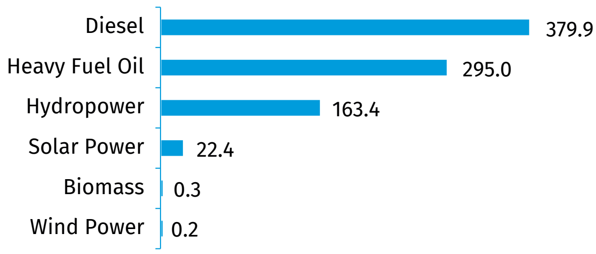
KEY FACTS

Population	26,923,353 (2021)[1]
Area	587,295 km^2[2]
Topography	Referring to its physical map, Madagascar has an asymmetry with respect to its main axis. The western part extends gently towards the Mozambique Channel, while the eastern part has a very steep slope leading towards the Indian Ocean. Topographically, the island can be divided into three main parts: the central highlands with an altitude ranging from 800 to 1,500 metres and a peak of 2,876 metres (Maromokotra), followed by the eastern slopes and finally the sedimentary zone of the north-west, west and south.[3]
Climate	Madagascar lies in the tropics and has two seasons and five main climatic regions comprising the East Coast, Uplands, West Coast, Southern and Sambirano regions. The cool, dry season begins in mid-April and ends in mid-October. The hot, rainy season begins in mid-October and ends in mid-April of the following year. The temperature is very varied in these areas but the absolute minimum of 1 °C is observed in the highlands (Antsirabe) in July, while the absolute maximum temperature was recorded in the extreme south at a value of 43.6 °C.[4,]
Climate Change	The trend of temperature increase has been significant in Madagascar since 1950. By 2055, the annual average temperature is projected to increase by 1.1 2.6 °C. Each region will have a variation in rainfall, but it is expected to be more intense in the western part. The number of more intense cyclonic disturbances has increased and the most affected areas have migrated towards the north-east of the island. As far as cyclones are concerned, the average annual number is not expected to change but the number of intense cyclones is expected to increase by 2100.[5,6]
Rain Pattern	Rainfall varies across the five climatic regions. Annual average rainfall exceeds 2,000 mm in the East Coast and in the Sambirano region. The Uplands, West Coast and Southern regions have an annual rainfall of 1,200, 950 and 600 mm, respectively. The annual minimum is 500 mm as observed in the South, which has a semi-arid climate. The maximum rainfall can be found in the East Coast, which has a hot and humid climate, at a value of 3,700 mm with 260 rainy days per year.[4]
Hydrology	There are more than 10 major rivers in Madagascar. Their tributaries constitute river networks scattered across different corners of the big island. The drainage pattern is a consequence of the asymmetric nature of the country's relief. As a result, the rivers in the west are longer, while those in the east are shorter and have a more accentuated course with numerous waterfalls, sometimes of considerable height. The periodic passage of tropical depressions, especially in the eastern and north-eastern parts of the country, makes the hydrological regimes extremely complex.[3]

ELECTRICITY SECTOR OVERVIEW

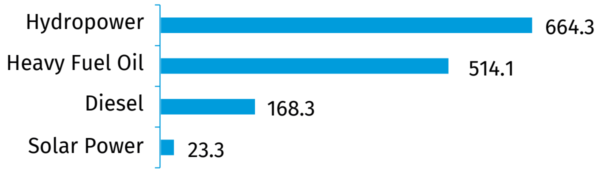
Madagascar uses several energy sources to generate electricity: hydropower, hybrid solar photovoltaic-diesel, heavy fuel oil and diesel. In 2020, 50.2 per cent of the produced electricity came from renewable sources, while 49.8 per cent came from fossil fuel sources. The total electricity generation in 2020 amounted to 1,370 GWh (Figure 1). Biomass and wind power plants are also used but in negligible proportions compared to the other sources. The total installed capacity of the country was 861.2 MW in 2020, with renewable sources accounting for approximately 22 per cent (Figure 2).[7]

Figure 1. **Annual Electricity Generation by Source in Madagascar in 2020 (GWh)**



Source: Ministry of Energy and Hydrocarbons[7]

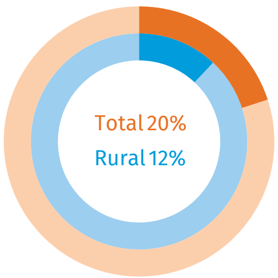
Figure 2. **Installed Electricity Capacity by Source in Madagascar in 2020 (MW)**



Source: Ministry of Energy and Hydrocarbons[7]

Madagascar does not import or export electricity due to a lack of geographical proximity to other countries. With regard to electricity access, the data collected by the Rural Electrification Development Agency (ADER) in January 2020 shows a national rate of almost 20 per cent, dividing the number of people with access to electricity infrastructure by the total population. Electrification rate is 12 per cent in rural areas and 67 per cent in urban areas.9

Figure 3. **Electrification Rates in Madagascar in 2020 (%)**



Source: ADER[9]

The electricity sector has been liberalized since 1999 following law No. 98-032 on the reform of the electricity sector. This liberalization is improved and confirmed by Law 2017-020 of 10 April 2018 on the Electricity Code of Madagascar.[8] Thus, the private sector is encouraged to finance all or part of the infrastructure through a contract signed with the Government for a fixed period of time.

The explanatory memorandum of the Electricity Code of Madagascar also specifies the attributions of the public sector.[8] The public sector is composed of the Ministry of Energy and Hydrocarbons, the Regulator and ADER. Since the adoption of the Electricity Code, ADER has been responsible for defining national electricity policy and coordinating the planning of all projects in the sector. Its remit is also the development of electrification in rural and peri-urban areas and the implementation of national policy in these areas.

Currently, Madagascar has three interconnected grids: RIA (Antananarivo), RIT (Toamasina) and RIF (Fianarantsoa), with the other major cities and rural villages supplied by off-grid power plants.[9] Two projects are being implemented for the interconnection of RIT with RIA first and RIA with RIF later, through the PRIRTEM I and PRIRTEM II projects supported by the African Development Bank and the European Union.[10]

Tariff regulation is the subject of an entire title of the Electricity Code of Madagascar.[8] It concerns sales of power and energy and their surpluses between the different actors in both interconnected and off-grid networks. The Regulator is empowered to approve the regulated tariffs. For national networks managed by national companies, four tariff zones are established according to the energy source that feeds them. In decentralized rural electrification, the tariff varies according to the business plan presented by the operator. In 2020, the average household electricity tariff was 0.120 USD/kWh and the average tariff for businesses was 0.118 USD/kWh.[11]

Several governmental decrees (notably Decree 2005-062 of 25 January 2005, Decree 2001-803 of 19 September 2001 and Decree 2003-194 of 4 March 2003) specify the role of the Regulator, which is responsible for the control of the electricity sector, including the determination and publication of regulated prices and fees, as well as the monitoring of their correct application.[12] The supervision of the respect of the quality-of-service standards, the control and respect of the competition principle, the mediation service, the follow-up and control of the execution of the concession and authorization contracts, the supervision of the elaboration of the Grid Code are also part of its attribution.[8]

SMALL HYDROPOWER SECTOR OVERVIEW

Madagascar does not have an official classification of hydropower plants. Thus, this chapter uses the definition of small hydropower (SHP) as plants with capacity up to 10 MW.

The installed capacity of SHP in Madagascar is 37 MW, of which 26.3 MW is available capacity. There are currently 36 installed SHP plants, of which 25 are operational. The other 11 with a total capacity of 0.5 MW require refurbishment.[16] Twenty-six of the plants, with a total capacity of 6.62 MW, are off-grid. Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed capacity increased by 12 per cent as a result of the commissioning of three new power plants (Figure 4, Table 1). The reason for the increase of the potential figures is access to more advanced and accurate data. According to the results of a study undertaken by ESMAP, which was completed in 2017, the unexploited theoretical potential of SHP up to 10 MW in Madagascar is 799 MW, making the total potential capacity 836 MW.[3] This study was performed by SHER consultancy using their internal software SiteFinder and based on an assumption of a 50 per cent annual average flow rate.

Several aspects hamper SHP development in Madagascar. Thus, turbine manufacturing is not yet well-developed in the country and most turbines are still imported, which increases the cost of project implementation. The maximum power of locally manufactured turbines is 100 kW, but their efficiency is not entirely satisfactory. Additionally, rainfall reference stations do not cover the entire territory and geographical interpolations are often required, which introduces error. The hydrological monitoring of the rivers and streams, on which SHP plants are developed, is insufficient. In fact, it is often the case that daily monitoring is organized at the time of the elaboration of the feasibility studies and subsequently stops when the services of the consulting firms hired to carry them out are completed.

Exchange with countries already advanced in turbine manufacturing and related technology transfer is strongly recommended to further develop the sector in Madagascar. In connection with the implementation of the SHP development programme, hydrological monitoring with the installation of rain gauges should be carried out at the sites planned for development and should be continuous even if the plant is already in operation.

SMALL HYDROPOWER PROJECTS AVAILABLE FOR INVESTMENT

As of early 2021, the following SHP projects were at an advanced stage of study and ready for development. They have been identified in the Indicative Regional Development Plans. The selection of operators for their development is subject to a call for tender.

Table 3. **List of Small Hydropower Plants Available for Development in Madagascar in 2021**

RENEWABLE ENERGY POLICY

Madagascar has ratified the Paris Agreement on climate change through Law 2016-019 and is currently developing a national strategy for each sector.[17] For the energy section, a consultation with all stakeholders was organized in February 2021. The Letter of Energy Policy 2015–2030 remains the official document containing quantified objectives in terms of renewable energy use.[18] The objective is to have an 85 per cent share of renewable energy sources in the energy mix by 2030, of which 75 per cent is to come from hydropower, 5 per cent from solar power and the remaining 5 per cent from wind power. To achieve this energy mix target, in 2015 the Government launched a call for tenders for the development of two hydropower plants: the Volobe project with a capacity of 120 MW and the Sahofika project of 205 MW.[19,20] As of early 2021, the future concessionaire had already been selected and the negotiations on the purchase contract and the concession contract were underway. In addition, the Government, which was elected in 2019, has set a target of doubling renewable energy capacity from 400 MW to 800 MW by 2023 and achieving a 50 per cent electricity access rate, including 40.8 per cent access in rural areas, where 80 per cent of the population lives. In rural areas this is to be achieved in part by the development of SHP with a total power of 35 MW until 2023, with the following phasing: 3 MW in 2021, 6 MW in 2022 and 26 MW in 2023.

According to Law 2017-020 of 10 April 2018 on the Electricity Code of Madagascar, tariffs should reflect costs. In the case of distribution to end customers, tariff setting must take into account the customers' ability to pay and the operator's financial equilibrium. This law also contains incentives for the use of renewable energy by providing for tax breaks. But the clauses on these measures are referred to in the finance law. In practice, these measures consist of customs duty exemptions and VAT exemptions. In the case of injection into the grid, priority is given to energy from renewable sources.

With regard to the price per kWh, the tariff applied on the national grid varies according to the energy source, with four tariff zones being distinguished. This difference can also be seen in the tariffs applied in isolated networks, where no standardization is carried out, but the fact remains that localities supplied by hydropower find their tariffs more affordable compared to localities served by other sources.

The development of a hydropower plant takes a long time and is not always in line with the promises made by candidates at election time. The elaboration and implementation of a multi-annual development programme for hydropower plants can contribute to policy decisions on SHP. Currently, a national electricity access strategy is being developed, and such a programme should be derived from this document as soon as it is finalized.

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

For the moment, the Government has not yet issued a specific policy for the development of SHP in the country. Concerning the existing regulations, a clear evolution is apparent since the adoption of Law 2017-020 compared to the former Law 98-032.[21] This is particularly the case for new thresholds of capacities submitted to each regulatory regime. For example, under the old law, an SHP plant of more than 150 kW would be classified under the concession regime, whereas under the new law this limit has been raised to above 5 MW. Currently, hydropower plants with a capacity of less than 500 kW are subject to the declaration regime and those between 500 kW and 5 MW fall under the authorization regime.

The awarding of a contract may be the result of a call for tenders launched by the Government or of an unsolicited application. Whatever the applicable regime, any developer must sign a contract with the Government represented by the Minister of Energy and Hydrocarbons or ADER as the case may be. According to the Electricity Code, an environmental study is mandatory before developing a project, with the requirements depending on the categorization of the project, as determined by the National Environmental Office.

COST OF SMALL HYDROPOWER DEVELOPMENT

The average cost of SHP development in Madagascar can be estimated at 3,278 USD/kW. This estimate is deduced from three power plants with capacities of 1.3–8 MW.[13] It should be noted that estimating cost per GWh generation remains difficult to produce. For SHP plants of 60–100 kW, out of the six projects already completed, the average cost is 3,632 USD/kW. It should be noted that these estimates only account for the generation, but not transmission and distribution costs.

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

Currently, there is no fund dedicated specifically to the development of SHP in Madagascar. The National Fund for Sustainable Energy (FNED), created by Law 2017-021 of 19 December 2017 is dedicated to financing projects focused on the use of renewable energy, of which SHP is a part, and energy efficiency. However, the fund is not yet functional.[22] The absence of a development bank in Madagascar also makes it difficult for project developers to obtain loans.

To date, most of the SHP projects carried out have been partly financed by the European Union, KfW, the German Agency for International Cooperation (GIZ), the United Nations Industrial Development Organization (UNIDO) or by foundations receiving grants from the environment or climate change funds. Projects are initiated either by the Government or by non-governmental organizations (NGOs). For the time being, the fund managed by UNIDO through the project Improving Access to Energy for Productive Use from Small Hydropower Plants in Rural Areas in Madagascar is the only one dedicated to activities related to SHP development in Madagascar. For SHP projects in rural areas, the Government generally participates either through the National Electricity Fund or through partners in investment subsidies. The payback period is 7–10 years for projects in rural areas subsidized at 70 per cent of the initial investment.[13]

The existence of some climate change related funds or funds from the Global Environment Facility are discussed informally and at meetings, but no clear communication has reached other sectors working on mitigation, such as energy. The same is true for carbon credits, where the process is still aberrant for project developers. Awareness raising in the relevant sectors is required.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The hydrological regimes of rivers in Madagascar are being disrupted by climate change and the forecasts made 10-20 years ago do not correspond to reality any longer. As recently as 2020, several large hydropower plants were operating at only 10 per cent of their capacity during low-water periods. No statistics are available at the moment on the effect of climate change on energy consumption in Madagascar.

The climate crisis, leading to the disruption of hydrological regimes, can distort estimates. Water availability due to exponential forest degradation, at a rate of one million hectares in 13 years (between 2004 and 2017), hampers the development of SHP in the country.[23] Environmental protection must be effective, including reforestation campaigns carried out with careful monitoring. The protection of the watersheds of each SHP project is among the priorities, with accompanying measures for stakeholders dependent on its exploitation before project implementation.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

In Madagascar, SHP development faces several key barriers, namely natural, financial, technical, communication and political ones. Importantly, the lack of a dedicated fund acts as a barrier to get projects off the ground. The effective operationalization of the FNED, with the concretization of the commitments of technical and financial partners, will contribute to the development of SHP projects. In addition, the establishment of a development bank would make it easier for project developers to obtain loans at reasonable rates. Systematic consultations with stakeholders in the energy sector during the budget and activity programme development phase related to the use of these funds will greatly contribute to the development of SHP.

The following points summarize the main barriers to SHP development in the country that have been identified:

- Turbines are mainly imported and not manufactured locally;
- Future risks associated with climate change as well as difficulty to attain hydrological estimates due to climate variability;
- Lack of a dedicated government fund;
- Insufficiency of rainfall monitoring systems in place;
- Lack of direct lines of communication for financing opportunities;
- Insufficient stakeholder consultation in the energy sector;
- Short election cycles incoherent with project development timescales.

The following points summarize the main enablers for the SHP sector that have been identified:

- SHP has an attractive cost per kWh compared to other renewable energy sources;
- The possibility of a new multi-annual development programme for hydropower derived from the national electricity access strategy;
- The availability of resources off-grid for SHP development.

Malawi

Gift Chiwayula, Department of Energy Affairs

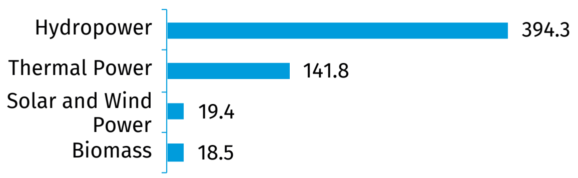
KEY FACTS

Population	19,129,952 (2020)[1]
Area	118,480 km^2 [2]
Topography	Malawi lies within the Great Rift Valley system. Lake Malawi, a body of water 580 kilometres long and lying at 460 metres above sea level, is the country's most prominent physical feature. Approximately 75 per cent of the land surface is a plateau lying at between 750 and 1,350 metres above sea level. Highland elevations rise to over 2,440 metres in the Nyika Plateau in the north and to 3,000 metres at Mount Sapitwa, the country's highest point. The lowest point is on the southern border, where the Shire River meets the Zambezi at 37 metres above sea level.[3]
Climate	The climate of Malawi is sub-tropical, with a rainy season lasting from November to April, a cool season between May and mid-August and a hot season from mid-August to November. Variations in altitude in Malawi lead to wide differences in climate, with the rainy season lasting longer in the northern and eastern mountains. Mean annual temperature is 24 °C, with average daily maximum temperatures in November reaching 29 °C, while dropping to 23 °C in July.[2]
Climate Change	In 2006, rise in average annual temperatures in Malawi was estimated at 0.9 °C over a 30-year period.[4] Several climate change models predict a countrywide increase of 1.4–3.2 °C in maximum temperature and a 1.6–2.9 °C increase in average annual temperatures by the mid-21st century, relative to the 1990s, with no significant seasonal difference in temperature rise. Over the same period, models predict a countrywide increase in annual precipitation of up to 25 per cent. On a regional level, precipitation is expected to increase in the north and decrease in the south.[5]
Rain Pattern	Precipitation is heaviest along the northern coast of Lake Malawi, where the average annual rainfall is more than 1,630 mm. Approximately 70 per cent of the country averages between 750 mm and 1,000 mm of precipitation annually.[3]
Hydrology	The main water source in the country is Lake Malawi, stretching along the eastern borders with Tanzania and Mozambique and accounting for approximately 20 per cent of the country's total area. The most significant river is the Shire (402 km), which is Lake Malawi's only outlet, flowing south into Mozambique where it meets the Zambezi.[3]

ELECTRICITY SECTOR OVERVIEW

As of June 2020, total installed capacity in Malawi amounted to 574.0 MW, of which hydropower contributed 394.3 MW (nearly 69 per cent of the total), conventional thermal power 141.8 MW (approximately 25 per cent), including 78.0 MW of emergency generators and 51.6 MW of peaking generators running on diesel, solar and wind power combined 19.4 MW (3 per cent) and thermal power from biomass 18.5 MW (3 per cent) (Figure 1). The major generating capacities are owned and operated by the Energy Generating Company (Malawi) Limited (EGENCO), with emergency generators, peaking generators and a number of other facilities including plants utilizing renewable energy sources (RES) operated by smaller private entities.[6,7,8,9,10]

Figure 1. **Installed Electricity Capacity by Source in Malawi in 2020 (MW)**



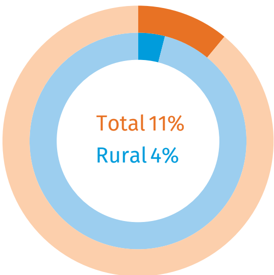
Source: Taulo et al.,[6] Chiwayula,[7] EGENCO,[8] Ministry of Finance, Economic Planning and Development,[9] USAID[10]

In 2019, annual electricity generation reached 1,887 GWh, a slight increase from the 1,808.6 GWh and 1,792 GWh generated in 2017 and 2018, respectively. However, in 2020 generation decreased across the country, with monthly generation in March 2020 only reaching 139.3 GWh, experiencing a steady decline from the 160.3 GWh generated in July 2019. As the overwhelming majority of electricity generation in

Malawi is provided by hydropower, low water levels in Lake Malawi and reduced flow in the Shire River in the second half of 2019 were responsible for this significant decline in output. Peak electricity demand and consumption have also fluctuated in recent years, with peak demand amounting to 299.6 MW in 2019 (down from 335.3 MW in 2015) and domestic consumption equalling 568.2 GWh in 2019 (down from 766.3 GWh in 2016). The main consumers of electricity in Malawi in 2019 were industry (44 per cent of total) and domestic users (36 per cent), with general use consumption (19 per cent) and exports (1 per cent) making up the remainder. At the same time, the number of individual consumers connected to the grid has more than doubled over the last decade, from 205,045 in 2011 to 439,187 in 2019. The Integrated Resource Plan developed by the Government of Malawi projects that peak demand will reach 1,158 MW by 2025 and 1,873 MW by 2030.[9]

In 2019, access to electricity decreased to just over 11 per cent nationally (4 percent in rural areas), from 18 percent (11 per cent rural) in 2018 (Figure 2).[11] Even for those with electricity access, supply is erratic and subject to frequent shortages and outages due to load shedding. The Government of Malawi has been looking to tap small-scale off-grid RES plants including solar power, wind power and small hydropower (SHP) to meet electricity demand in isolated areas where grid extension is difficult, aiming to increase nationwide access to electricity to 30 per cent by 2030.[9,12]

Figure 2. **Electrification Rate in Malawi in 2019 (%)**



Source: World Bank[11]

Electricity generation in Malawi is primarily carried out by EGENCO, created after the unbundling of the Electricity Supply Cooperation of Malawi (ESCOM). ESCOM, which previously was the sole provider of on-grid electricity in Malawi, has been unbundled into three companies, with EGENCO responsible for generation and operating all the major hydropower plants in the country. Power Market Limited (PML) is responsible for buying the generated electricity and ESCOM itself is responsible for transmission and distribution. Additionally, some generation is carried out by independent power producers (IPPs) that include Mulanje Hydro Limited as well as Aggrekko, which operates the emergency diesel-fuelled generators.[7]

Electricity tariffs differ depending on the type of customer and the phase supply being used and are lower than the tariffs in the South African Development Community (SADC) region and other neighbouring countries. The tariffs are regulated by the Malawi Energy Regulatory Authority (MERA), which is also the main regulator of all other fuels.[13] Tariffs for domestic, commercial and industrial users as of 30 March 2020 are displayed in Table 1.

Table 1. **Electricity Tariffs in Malawi in 2021**

Type of customer	*Description*	*Tariff (USD/kWh)*
Domestic	Single phase supply	0.0978
	Three phase supply	0.1420
Commercial	Single phase supply	0.1471
	Three phase supply	0.1627
Industrial	On-peak	0.1790
	Off-peak	0.0621

Source: ESCOM[14]

The Government of Malawi is making efforts to increase the capacity of generated electricity through upgrades to existing power plants and the construction of new ones, planning to increase annual generation to 3,300 GWh by 2030. Feasibility studies are currently underway for various energy sources, including hydropower, coal, biomass, geothermal power and wind and solar power. As of 2020, the Government had signed 11 power purchase agreements (PPAs) with developers to install an additional 328 MW of capacity by 2027. Plans are also underway to connect to the Zambian and Tanzanian power grids, providing investors with access to regional power markets including the Southern Africa Power Pool (SAPP). Programmes such as the Malawi Rural Electrification Programme (MAREP) and Malawi Electricity Access Project (MEAP) are ongoing with the aim of expanding electricity access in both rural and urban areas.[8,9]

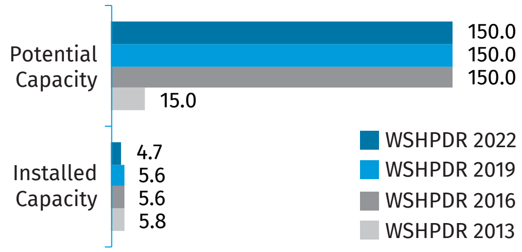
In general, the electricity sector in Malawi faces many challenges, including lack of IPPs and lack of financial resources and clear policy guidelines to promote private investors in the electricity sector. Additionally, shifting weather patterns have been creating instability in hydropower generation, requiring the procurement of emergency diesel generators in order to meet demand. In 2013, the Millennium Challenge Corporation provided the Government of Malawi with funds totalling USD 350.7 million in order to help overcome some of these challenges.[15]

SMALL HYDROPOWER SECTOR OVERVIEW

In Malawi, SHP is defined as hydropower plants with an installed capacity of less than 5 MW. As of 2021, total installed capacity for SHP plants under 5 MW in Malawi was approximately 4.7 MW, while SHP capacity up to 10 MW was 12.9 MW.[7,16,17,18] Based on studies of previous years, proven SHP potential amounts to at least 7.7 MW and theoretical potential has been estimated at 150 MW.[19,20] This indicates that approximately 4 per cent of the country's known theoretical SHP potential has been developed so far. Compared to data from the *World Small Hydropower Development Report*

(WSHPDR) 2019, the installed capacity for SHP up to 5 MW has decreased marginally as more precise data on operational plants became available and also due to the replacement of older SHP plants with a new SHP plant of over 5 MW installed capacity.[21]

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Malawi (MW)**



Source: Ministry of Energy and Mining,[3] Taulo et al.,[6] Chiwayula,[7] Gilkes,[16] Ministry of Energy,[17] Jonker Klunne,[18] Kaunda et al.,[19] *WSHPDR 2019*,[20] *WSHPDR 2013*,[21] *WSHPDR 2016*[22]

Note: Data for SHP up to 5 MW.

As of 2021, the Wovwe SHP plant in Karonga is the only grid-connected SHP under 5 MW operating in Malawi, with an installed capacity of 4.35 MW.[23] The 8.25 MW Ruo-Ndiza SHP plant in Mulanje, another grid-connected power plant that falls under the up to 10 MW definition of SHP, was operational as of 2020 and is the largest SHP project in Malawi. The plant, located at the Lujeri Tea Estates, replaced two old SHP plants of 0.84 MW and 0.46 MW at the same location.[16,18] Additionally, several mini- and micro-hydropower plants are operational on isolated mini-grids, including two plants of 60 kW and one 100 kW plant that are part of the Mulanje Electricity Generating Agency (MEGA) mini-grid in Bondo, the 70 kW Chipopoma SHP plant and the 10 kW Kavuzi SHP plant.[17,24,25] Operational SHP plants are listed in Table 2.

Ongoing SHP development includes the construction of another 4.5 MW power plant at the Wovwe site to bring the total installed capacity of the plant to 9.5 MW.[23] Additionally, upgrades have been planned to the MEGA group of SHP plants by a non-governmental organization called Practical Action to bring the entire network to 2 MW of capacity. Components of the Practical Action programme originally included the development of several new SHP plants of up to 500 kW capacity, aiming to reach an annual SHP generation target of 15.6 GWh, with funding provided by the Global Environment Facility (GEF) and the Government of Scotland. Completed upgrades have brought the MEGA mini-grid to its current capacity of 220 kW. Also, a grant was awarded by EEP Africa to Practical Action to develop an SHP plant at Usingini with an initial planned capacity of 300 kW and a total potential capacity of 5 MW. However, Practical Action has recently reduced its presence in Malawi and additional MEGA upgrades as well as the Usingini project have been delayed, with the latter in advanced stages of planning.[7,17,24] Ongoing SHP projects are listed in Table 3.

Table 2. **List of Operational Small Hydropower Plants in Malawi**

Name	*Location*	*Capacity (MW)*	*Head*	*Plant type*	*Operator*	*Launch year*
Ruo-Ndiza	Mulanje, Lujeri Tea Estate	8.250	230	Run-of-river	Mulanje Hydro Ltd	2020

Several other previously functional SHP plants are currently out of operation, including one in Matandani maintained by the Malawi Industrial Research and Development Centre, as well as the Kongwe and Malosa SHP plants. These sites, with a total installed capacity of 358 kW when operational, could be potentially refurbished. Additionally, the Malawi Rural Electrification Programme (MAREP) Master Plan Study carried out by the Japan International Cooperation Agency (JICA) identified 33 potential SHP sites, including 11 promising sites with a total estimated potential capacity of 345 kW.[7,18,26] Several potential sites for SHP plant construction or refurbishment are listed in Table 4.

Table 4. **List of Selected Potential Small Hydropower Sites in Malawi**

Name	*Location*	*Potential capacity (kW)*	*Type of site (new or refurbishment)*
Matandani	Neno district	28	Refurbishment
Katowo	Hewe River	45	New
Ruarwe	Lizunkhuni River	50	New
Nthalire	Choyoti River	60	New
Sandama	Nswazi River	75	New

RENEWABLE ENERGY POLICY

The new National Energy Policy (NEP) of Malawi, issued in 2018, and the Malawi Renewable Energy Strategy, developed in 2017, both provide for the development of RES in the country. The 2018 National Energy Policy aims to increase hydropower capacity, extend the national grid as well as expand the implementation of mini-grids in remote areas based on hydropower generation. Increases in hydropower capacity and output are to be achieved through the construction of new plants by IPPs as well as upgrades to existing plants. While hydropower is expected to provide the bulk of the country's generation, the Policy also outlines diversification into other energy sources including solar power, wind power and coal.[27]

The Malawi Renewable Energy Strategy includes the following elements:

- Incentives for RES technologies including tax waivers, which have been put in place starting with the 2020/2021 fiscal year to reduce the cost of RES development;
- Promotion of research and development in RES and increasing the number of undergraduate and graduate courses in RES offered by technical universities in Malawi, as well as training programmes in RES offered by other stakeholders;
- Awareness campaigns by various media organizations to promote RES;
- Establishment of the Malawi Renewable Energy Partnership Group (MREPG) in 2018 to oversee the implementation of RES projects in Malawi and provide coordination for RES stakeholders;
- The implementation of feed-in tariffs (FITs) and a PPA framework for RES, still in development stages.[28]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

SHP development in Malawi is covered by regulations applied to hydropower in general, outlined in the National Energy Policy. Legislation on hydropower in Malawi differentiates between grid-connected and stand-alone (off-grid) projects. In the case of grid-connected projects, the developer is given the generation licence only, after meeting the necessary technical, safety and environmental requirements, which include an environmental impact assessment. Power from grid-connected hydropower IPPs is sold to Power Market Limited and distributed exclusively by ESCOM. In the case of off-grid projects, hydropower plants (including SHP plants) can operate as a mini-grid where the developer is given generation, transmission and distribution licences after meeting the necessary requirements. Some of the requirements are that the system should be of the same standard as the main grid for easy integration and sell electricity at a tariff approved by the Malawi Energy Regulatory Authority.[27,28]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

Financial support for SHP development in Malawi is provided by a variety of international and local entities. International organizations providing funding for SHP have included the World Bank, the United Nations Development Programme (UNDP), the European Union Energy Facility, the Organization of the Petroleum Exporting Countries (OPEC) Fund for International Development and the Global Environmental Facility Small Grants Program (GEF SGP).[7,17,24,25] Bilateral support for RES and hydropower development has been provided by the United States Government through the United States Agency for International Development (USAID) and the Millennium Challenge Corporation (MCC), while the Japan International Cooperation Agency (JICA) and the Scottish Government have supported projects specifically focused on SHP.[10,15,26] Local funding for SHP has also been provided by the Ministry of Energy as well as by private investors and international non-governmental organizations with a presence in the county.[17]

COST OF SMALL HYDROPOWER DEVELOPMENT

Costs of SHP development in Malawi have varied considerably based on project size and location. The recently commissioned Ruo-Ndiza 8.25 MW SHP plant carried a total project cost of USD 16 million, or 1,939 USD/kW.[30] The Usigini SHP project with a preliminary capacity of 300 kW and eventual planned capacity of 5 MW was initiated with funds totalling USD 328,125 (1,093 USD/kW), but has been affected by severe delays.[17] On the other end of the spectrum, JICA's Master Plan Study for MAREP estimated construction costs of between USD 299,890 and USD 1,213,930 for 11 prospective sites of 5–75 kW, averaging between 12,629.2 USD/kW and 94,690 USD/kW.[26] From these figures it becomes clear that micro-hydropower projects in Malawi are significantly more expensive than projects in the 1–10 MW range.

EFFECT OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Malawi is heavily dependent on hydropower for electricity production and has already been experiencing severe generation shortfalls due to low water levels in Lake Malawi and the Shire River, particularly in 2020.[9] Extreme fluctuations in rainfall have also caused flooding, causing damage to hydropower infrastructure. Projections of future weather pattern changes by the mid-21st century predict an increase in rainfall in the northern part of the country (up to 40 per cent during the wet season) and a decrease in the south (up to 75 per cent during the dry season). Significantly, several climate models predicted an increase in runoff of nearly 182 per cent during the wet season in the northern part of the country and a moderate 11 per cent decline in the south.[5] These data suggest that SHP in Malawi is threatened not only by water scarcity but also by the increased likelihood of flood damage, particularly in the north.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Some of the key barriers to SHP development in Malawi include:

- The lack of investors to develop SHP due to limited financing capacity;
- Environmental degradation, with deforestation from logging and farming activities upstream and near the river banks leading to rivers drying up;
- Lack of human capital to build and operate SHP plants in Malawi;
- Lack of information and awareness among communities on the benefits of SHP;
- Old electricity infrastructure vulnerable to extreme weather events;
- Vandalism of infrastructure such as transformers.

Enablers for SHP development include:

- Acute demand for additional generation capacity due to very low electrification rate in the country;
- Availability of financing mechanisms;
- Tax exemption on all RES equipment;
- Availability of detailed data on potential SHP sites and large untapped SHP potential;
- Existing political will to develop the energy sector.

Mauritius

Dinesh Surroop and Doorgeshwaree Jaggeshar, University of Mauritius

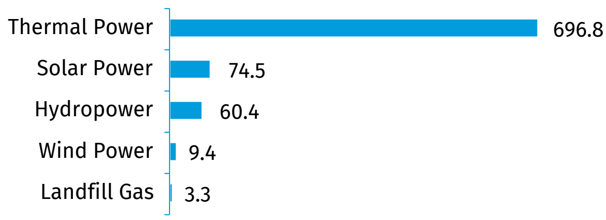
KEY FACTS

Population	1,265,475 (2019)[1]
Area	1,868 km^2 [1]
Topography	The island, located in the south-west of the Indian Ocean, was formed by volcanic activity. It has sandy beaches and fringing coral reefs, which surround most of the 322 kilometres of its coastline. The topography is categorized by undulating plains in different parts of the island and the highest point is 828 metres, which is located at Petite Riviere Noire.[2,3]
Climate	Enjoying a mild and tropical weather, the climate in Mauritius is divided into two seasons, namely summer and winter. Summer is warm and humid and it runs from November to April and winter is cool and dry lasting from June to September. October and May are the transition months. The mean temperature during summer is 22.7 °C; the climate is moderately hot and moist. During the winter the average temperature is 18.7 °C, with a relatively chilly and drier climate.[4,5]
Climate Change	Observed climate change impacts have indicated a warming trend on the island, with the average temperature at all stations rising at the rate of 0.15 °C per decade and has already risen by 0.74 1.2 °C when compared to the 1961-90 long term mean. Meanwhile a diminishing trend in annual rainfall has also been shown. In spite of the decreasing number of rainy days, the recurrence of extreme climate events, overwhelming downpours and storms with strengths equivalent to tropical cyclones or higher has expanded over the last two decades. Future projections of climatic changes anticipate a decrease of approximately 10 20 per cent in rainfall and a temperature increase of 2 °C.[2,4,6]
Rain Pattern	The annual precipitation for the year 2020 was approximately 1,993 mm, indicating a decrease by 6 per cent from 2019. The annual average rainfall from 1971 to 2000 amounted to 2,010 mm. Despite no fixed rainfall period, rainfall generally occurs during summer months, with an annual average summer rainfall of 1,322 mm (1971–2000). In the winter season, the annual average rainfall is 666 mm.[4,7]
Hydrology	The hydraulic system of Mauritius is composed of 20 main rivers with the Grand River South-East, located in the central-eastern region, having the longest length of approximately 28 kilometres. Other primary waterways include the Black River, Post River, Grand River North-west and Rempart River. Mauritius also has a few waterfalls and 10 main man-made reservoirs. The reservoirs amount to a total capacity of approximately 67.4 m^3.[2,8]

ELECTRICITY SECTOR OVERVIEW

In 2019, the total power plant installed capacity in the island amounted to 844.3 MW (Figure 1), while the total effective capacity was 771.9 MW. Electricity generation in 2020 reached 2,882 GWh (Figure 2), with the peak power demand reaching 494 MW.[9] The bulk of electricity production in Mauritius comes mainly from fossil fuels, namely coal and oil, followed by renewable energy sources including bagasse, hydropower, solar power, wind power and landfill gas. In 2020, coal and oil represented 76 per cent in the electricity production mix and the rest (24 per cent) was met by renewable energy at 688 GWh.[8] Hydropower represented approximately 4 per cent of all generation, at 115.8 GWh.[7]

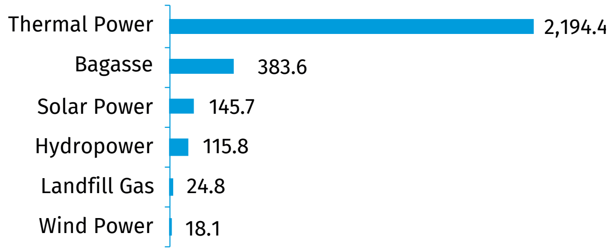
Figure 1. **Installed Electricity Capacity by Source in Mauritius in 2019 (MW)**



Source: MREPU,[9] CEB[15]

Note: According to MREPU, bagasse is included in the thermal installed capacity figures.

Figure 2. **Annual Electricity Generation by Source in Mauritius in 2020 (GWh)**



Source: CSO[7]

In the 1950s, the state-owned Central Electricity Board (CEB) was the only entity responsible for generating, transmitting and distributing electricity across the island until the sugar industry-affiliated power plants initiated the sale of electricity produced from bagasse to the CEB. This initiative was further encouraged by the Bagasse Energy Development Programme (BEDP) in 1991 and the Multi-Annual Adaptation Scheme 2006–2015.[10] Today, electricity in Mauritius is produced by the CEB and Independent Power Producers (IPPs). The share of the CEB's production in 2019 was 45 per cent, while the remaining 55 per cent was purchased from IPPs, which are mainly from the sugarcane industry.[8]

Mauritius has achieved an electrification rate of 100 per cent. The national rural electrification programme was established in 1983, allowing the connection of 153 villages and housing estates to the grid network. With an enlarged economy, Mauritius now enjoys extensive power provision infrastructure and the advantages of a steady power supply.[11]

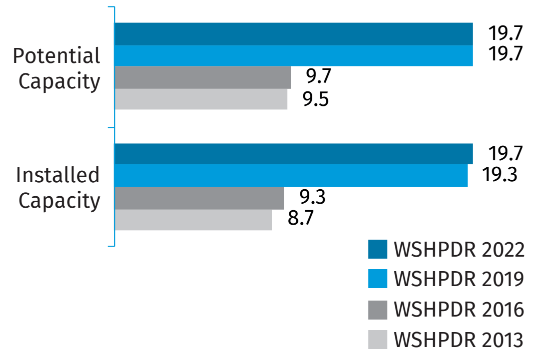
For most power projects, the Government of Mauritius looks for competitive international bids and favours collaboration between regional private bodies and international organizations. In 2017, the CEB Act (1963) was amended to permit CEB (Green Energy) Co Ltd, an entirely owned subsidiary of the CEB, to participate in power generation from renewable energy sources.

In 2019, the CEB's tariff programme had 24 different types of tariffs, ranging from 3.16 MUR/kWh (0.074 USD/kWh) for low-end residential consumers to a flat rate tariff of 10.01 MUR/kWh (0.023 USD/kWh) for commercial energy users.[12] It should be noted that special consideration has been made on social grounds for household electricity consumption. For instance, the Social Tariff 110A is applicable to households receiving the government social allowance, registered as socially vulnerable or registered under Tariffs 110 and 120 (excluding small-scale distributed generation owners) and meeting the required monthly consumption conditions.[13] However, it should be noted that electricity tariffs are not wholly cost-effective in Mauritius as industrial tariffs are subject to cross-subsidization. With no independent power utility regulator, the CEB is solely responsible for setting the tariffs. For this reason, proper planning is required for restructuring the tariff system, emphasizing the need for cost-effective production during capacity expansion.[14]

SMALL HYDROPOWER SECTOR OVERVIEW

There is no formal definition of small hydropower (SHP) in the country. This chapter uses the 10 MW definition. In 2020, the installed capacity of SHP in Mauritius amounted to 19.69 MW, indicating an increase of 0.35 MW compared to the *World Small Hydropower Development Report (WSHPDR) 2019* (Figure 3). The known potential capacity has not changed, indicating that the full known SHP potential has been exploited in the country. At present, there are 11 SHP plants including the recent Bagatelle Dam, which was commissioned in 2019 (Table 1). All SHP plants in the country, except for Riche en Eau and Bois Cherie, are owned by the CEB.

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Mauritius (MW)**



Source: CEB,[15] MEPRU,[16] WaterPower Magazine,[17] Bowers et al.,[18] *WSHPDR 2013*,[19] *WSHPDR 2016*,[20] *WSHPDR 2019*[21]

Apart from the Bagatelle Dam, Midlands Dam and La Nicoliere, the operational lifetime of the remaining SHP plants exceeds 50 years. The most ancient is the Reduit (now A.I.A.) SHP plant, which was established in 1906 but refurbished in 1984. Major hydropower refurbishments projects included the refurbishment and upgrading of the generating unit in the Magenta plant, which was expected to be completed by November 2019 (Table 2).[15] Although not an SHP project as such, but rather a project to increase the capacity of the 28 MW Champagne hydropower plant, the Sand Souci dam is to be fitted with a labyrinth type fuse gate, effectively increasing the generation of the nearby plant by 3 GWh.[22]

Table 1. **List of Operational Small Hydropower Plants in Mauritius**

Name	Capacity (MW)	Head (m)	Plant type	Operator	Launch year
Bagatelle Dam	0.35	–	Run-of-river with dam storage	CEB	2019
Midlands Dam	0.35	–	Run-of-river with dam storage	CEB	2013
La Nicoliere	0.35	–	–	CEB	2010

Name	Capacity (MW)	Head (m)	Plant type	Operator	Launch year
La Ferme	1.20	127	Run-of-river	CEB	1988
Le Val	4.00	183	Run-of-river with dam storage	CEB	1961
A.I.A (previously Reduit)	1.20	50	Run-of-river	CEB	1984
Ferney	10.00	123	Run-of-river	CEB	1971
Cascade Cecille	1.00	76	Run-of-river	CEB	1963
Magenta	0.94	45	Run-of-river with dam storage	CEB	1960

A full feasibility study determining potential SHP sites for setting up mini- and micro-hydropower plants is yet to be completed. There is a debate around whether the country's hydropower potential has been entirely exploited, as one modelling exercise claimed that full potential has been reached, whereas proponents of SHP in the country contested this study, arguing that "the predictions did not fully consider mini- and micro-hydropower plants, which have gained momentum and been helpful in reducing pressure on the main grid".[10,23] The Integrated Energy Plan (2013–2022) indicated the Government's interest in developing mini- and micro-hydropower plants in viable locations. However, with the exception of the Bagatelle Dam, no other initiative was taken in this direction.

RENEWABLE ENERGY POLICY

In 2008, the Government brought forward the Mauritius Sustainable Island (MID) policy, strategy and action plan with the vision of delivering sustainable growth and making Mauritius an example of sustainable development. The objective of the MID project was to achieve 35 per cent of renewable energy generation by 2025, by exploring additional economic incentives to advance the development of renewable energy resources. In parallel to the MID plan, financial support was obtained from the Government for several renewable energy projects. These include the setting of a 9.4 MW wind farm at Plaine des Roches, which was commissioned in 2015, and the installation of solar photovoltaic farms amongst others.[24]

Following the Integrated Energy Plan (IEP) 2003–2012, it was noted that little advancement occurred in the introduction of renewable energy technologies in the country. Hence, the Government came up with the Long-term Energy Strategy 2009–2025 with the objectives to reduce dependency on fossils fuels, promote long-term sustainable development and augment the share of renewable energy in the electricity mix to 35 per cent by 2025. The renewable energy development pathway advocated laid emphasis on an increasing share of bagasse-based energy, while setting targets for fossil fuels and green energy.[16]

Another IEP (2013–2022) was adopted by the CEB with the goal of ensuring a secure electricity future in Mauritius. According to the new IEP, the CEB has already begun feasibility studies to identify potential sites for further hydropower development.[25] The master plan's pillar has been to maximize the use of the current power grid, keep energy costs down, promote demand-side management and create opportunities for the private sector. According to the IEP, a 20 MW wind power plant would be installed every three years after 2017 and a 10 MW solar power plant every three years after 2013. However, the plan to install any 20 MW wind farm is yet to be accomplished.[26]

The CEB Small-Scale Distributed Generation (SSDG) Net-Billing Scheme was announced in the 2018/19 budget speech. Under the scheme, residential customers (who consume up to 100 kWh per month and are in tariff categories 110, 120, and 140) will generate their own electricity as part of a project aimed at promoting renewable energy. The SSDG project is to be implemented in three stages over the course of three years.[27] The scheme employs a net-billing system and 2,500 residential customers will be able to receive up to 100 kWh of electricity free of charge per month for the next 20 years, depending on their consumption. Taking current tariffs into account, the selected customers consuming less than 100 kWh per month will have their electricity completely free.[22]

In the energy sector, the Government has been working on legal and structural reforms. The Mauritius Renewable Energy Agency (MARENA) was established by the Government in 2016 to encourage the use of renewable power in the island.[28] In 2019, the Government came up with the Renewable Energy Roadmap 2030 for the Electricity Sector, where bagasse is the predominant renewable resource followed by solar power, waste-to-energy, hydropower and wind power.[9] Under the 2030 roadmap, the share of hydropower in total electricity generation should decrease from 4.4 to 2.5 per cent by 2030.

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

Securing a licence of Environmental Impact Assessment (EIA) is essential for mini- and micro-hydropower projects. The Government's strategy has been to enable Small Independent Power Producers (SIPPs), whether residential, industrial or commercial, to join the electricity supply market by installing small generating units of mainly solar photovoltaics and wind power. A grid code has been implemented to allow SIPPs generating below 50 kW of electricity for their personal use to feed any excess into the national grid system. To facilitate such a scheme, government initiatives, such as removal of a standby charge on renewable energy, were introduced.[16]

COST OF SMALL HYDROPOWER DDEVELOPMENT

Data for cost estimates of SHP development in the island are not available. However, a cost of approximately MUR 7.1 billion (USD 170 million) has been estimated for the construction of a new dam of 14.3 m^3 capacity.[29] For hydropower plants in Mauritius, the levelized cost of energy is approximately 0.020 USD/kWh, including other associated costs, such as maintenance, refurbishment and upgrading of power plants.[9]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

Funding for projects in the hydropower sector depends on the readiness of the project and the ability of the developer to implement the project. The water resources unit, under the Ministry of Finance and Economic Development, provides financing facilities in the form of grants. Estimates for the year 2017/2018 indicate an allocation of MUR 487 million (USD 11.4 million) for the construction of dams on the island.[29]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The longer drought period and decreasing rainfall trend pose a challenge to the availability of water resources in the country and thus for SHP development.[9] However, hydropower development is not only subjected to climate effects. As a small developing island country, governmental priority is being given to water use for household consumption purposes, rather than hydropower generation.[9,30]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Compared to other power generating units, hydropower plants are flexible to fluctuating electricity network demand. Hydropower plants have the capacity to quickly increase or decrease output and can provide electricity at peak demand conditions.[18] Recommendations suggest a possible revamping of the hydropower sector in Mauritius through the deployment of mini- and micro-hydropower plants or pumped storage plants to cater to the intermittency of renewable energy sources.[9] The potentiality of further hydropower development in the island is known to be limited. Exploring mini-and micro-hydropower is still possible and the Government is keen to explore this potential across the island. The CEB has already begun feasibility studies to identify potential sites for further hydropower development. However, while revamping any hydropower facilities is possible, striking the optimum balance between hydropower uses and environmental impact on the restricted island ecosystem is essential.

The following points summarize the main barriers to SHP development in Mauritius that have been identified:

- Only some locations possess the natural characteristics for exploitation (most cost-effective sites have been explored);
- Potable supply, agriculture and electricity generation compete for the water stored in reservoirs;
- Dependency of the technology on rainfall, while climate change is influencing rainfall patterns;
- The potential to expand the existing dam capacity is limited;
- High cost associated with hydropower plant construction;
- Lack of resources to conduct feasibility studies;
- Environmental impact of SHP.

The following points summarize the main enablers for SHP development that have been identified:

- Government feasibility studies are underway to determine whether new potential will be available.

Mozambique

Laura Stamm, International Center on Small Hydropower (ICSHP)

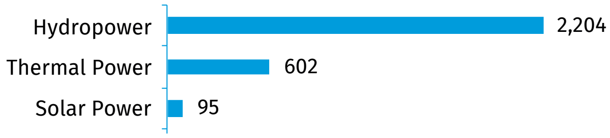
KEY FACTS

Population	32,163,045 (2021)[1]
Area	799,380 km² [2]
Topography	Mozambique is a topographically diverse country. The northern and western regions are predominately mountainous, while low lands cover the southern regions. There are five distinct highland regions. The Lichinga Plateau occupies the north-westernmost area along the border with Tanzania, followed by the Angonia Highlands on the north-western border with Malawi. The Maravila Highlands are found in the western pocket of land on the border with Zambia and just underneath is the Chimboio Plateau along the western border with Zimbabwe. The highest point in the country, Mount Binga at 2,436 metres, is found in the Chimboio region. The Mozambique Plateau occupies most of the northern interior, leaving a very narrow coastal plain in the north-east. In the south and south-east, where the Mozambique Plains are found, are the lowest elevations in the country, while small hills are found in the south-westernmost region.[2]
Climate	The country's climate is mostly tropical, though the south is slightly cooler than the north. The hottest temperatures, often reaching above 30 °C, are found along the north-eastern coastline especially during the summer months between December and February. The coldest temperatures, reaching 10 °C, are found in the highest altitudes along the western borders. Humidity varies greatly between regions. The northern and north-eastern regions are especially humid all year while the south is drier with a small semiarid area in the south-east.[2]
Climate Change	There has been a trend of rising temperatures in Mozambique in the past decades, which is expected to continue. The country is vulnerable to extreme weather events, particularly droughts, flooding and cyclones. These types of events have been on the increase since the 1970s. In the upcoming decades, droughts and floods are expected to become more intense and cyclones more prevalent.[3]
Rain Pattern	Rainfall varies greatly between regions and areas of the country. The northern and north-eastern regions are the wettest, with an average annual rainfall of between 1,000 mm and 1,780 mm with some pockets of over 2,000 mm. The west and southern interior receive the least rainfall, with annual averages between 600 mm and 800 mm. The semiarid region in the south-west receives an average of 300 mm in rainfall per year. The wet season throughout the country is between November and February, while the dry season is between April and October.[2]
Hydrology	Mozambique is a water-rich country. The major rivers flow eastwards from the western highlands to drain into the Mozambique Channel and Indian Ocean. The largest river in the country is the Zambezi flowing 819 kilometres through the central region. The major rivers in the north include the Rovuma that creates the country border with Tanzania, the Messalo, Lurio and Ligonha. The major rivers in the south include the Buzi, Save, Changane and Limpopo. Rivers tend to have a seasonal flow, flooding during the end of the wet season and are slow during the end of the dry season. The largest lakes are along the border with Malawi including Lake Nyasa and Lake Chilwa.[2]

ELECTRICITY SECTOR OVERVIEW

In 2020, the total installed capacity in Mozambique was 2,915 MW. Of this, hydropower accounted for 2,204 MW (just under 76 per cent), thermal power for 602 MW (21 per cent), solar power for 95 MW (3 per cent) and biomass for 14 MW (0.5 per cent) (Figure 1).[4] The country's energy mix has been dominated by hydropower since the opening of the Cahora Bassa plant in 1974. In the past few years, the country has been diversifying into other renewable energies, with strong focus on solar power. The country's first large-scale solar power plant, with an installed capacity of 40 MW, opened in 2019 and is located in Mocuba. Shortly after, in 2020, an additional 41 MW solar power plant was commissioned in Metero by French-owned power producer, Neoen.[5]

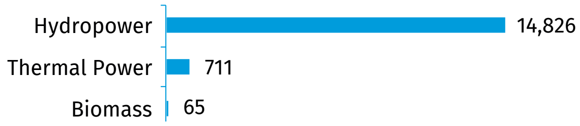
Figure 1. **Installed Electricity Capacity in Mozambique by Source in 2020 (MW)**



Source: IRENA[4]

The total electricity generated in 2019 in Mozambique was 15,603 GWh. Of this, hydropower generated 14,826 GWh (95 per cent), thermal power 711 GWh (over 4 per cent) and the last percentage was split between 65 GWh of biomass and 2 GWh of solar power (Figure 2).[4] As more recent data are not available, this does not reflect the electricity generated by the new Mocuba solar power plant which has an estimated generation capacity of 79 GWh/year.[5]

Figure 2. **Annual Electricity Generation in Mozambique by Source in 2019 (GWh)**



Source: IRENA[4]

The Electricity Law of 1997 first allowed independent power producers (IPPs) to participate in the supply of electricity in Mozambique. Prior to this, state-owned Electridade de Moçambique (EDM) was the main electricity supplier, with the exception of Hidroeléctrica de Cahora Bassa S.A. (HCB), and still holds a significant market share of electricity generation. HCB, which operates the one large hydropower plant with an installed capacity of 2,075 MW was once mostly owned by REN of Portugal, but since 2007 the majority ownership has been transferred to the Government of Mozambique, which currently owns over 92 per cent of the shares. In recent years IPPs have played an important role in the electricity sector. The largest IPPs include Central Termoelectrica de Ressano Garcia (CTRG) with an installed capacity of 175 MW, Gigawatt Ressano Garcia with 110 MW, Nacala floating powership with 102 MW, Kuvaninga with 40 MW and Aggreko with temporary contracts of 122 MW and 107 MW. As EDM is responsible for the distribution and transmission of electricity in the county, these IPPs operate within power purchase agreements (PPAs) with EDM.[6]

The Ministry of Natural Resources and Energy (MIREME) is responsible for supervising operation and development in the electricity sector. The Energy Regulatory Authority (ARENE) is the organization responsible for regulating the sector. EDM makes the final approval of tariffs for end customers. Different tariffs are determined for five different types of consumers: low voltage, major consumers of low voltage, medium voltage, agriculture medium voltage and high voltage.[6] Social tariffs with a special rate are provided for some low-voltage customers for 0.97 Mt/kWh (0.015 USD/kWh). The regular tariffs prices for all other customers are listed in Table 1.[7]

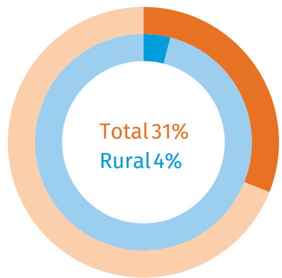
Table 1. **Electricity Tariffs in Mozambique**

Type of consumer	*Tariff (MZN/kWh (USD/kWh))*
Low voltage households:	
< 200 kWh	6.00 (0.094)
200–500 kWh	8.49 (0.130)
> 500 kWh	8.91 (0.140)
Major low voltage	5.74 (0.090)
Medium voltage	4.78 (0.075)
Medium voltage (agricultural)	2.72 (0.043)
High voltage	4.70 (0.074)

Source: EDM[7]

The electrification rate of Mozambique in 2020 was just under 31 per cent, which includes an urban rate of 75 per cent and a rural rate of just above 4 per cent (Figure 3).[8] The current policy objectives of the Government and EDM are focused on rural electrification and increasing the number of new users on a continuous basis. While many extensions have been carried out since 2007, there is still much to be accomplished in order to meet targets. The most recent national plans include targets of reaching a 50 per cent electrification rate by 2023 and universal access by 2030. To push this agenda, the Government of Mozambique partnered with the World Bank to draw up the National Electrification Plan in 2018. As a result of the plan, the World Bank approved a USD 82 million direct grant along with a USD 66 million grant through a Multi Donor Trust Fund (MDTF) to expand and densify the national grid and implement off-grid solutions in some remote places.[9]

Figure 3. **Electrification Rate in Mozambique in 2020 (%)**



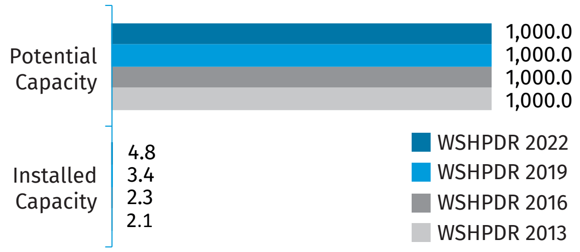
Source: World Bank[8]

Improving infrastructure quality is another main focus in the energy sector. Due to structural inefficiencies and far distances between generation and consumption, distribution and transmission losses are substantial. In 2017, losses amounted to approximately 26 per cent. In response, projects to strengthen the transmission network have been undertaken and will continue to be important. Furthermore, the current capacity will not be sufficient to bring electricity to the whole population. To address this, several sites have been identified for future projects. Many of the large-scaled projects are with hydropower, namely Mphanda Nkuwa (1,500 MW), HCB North bank (1,245 MW), Lupata (600 MW), Boroma (200 MW) and Lurio (120 MW). Solar power projects are also substantial, including 43 on-grid projects that amount to 599 MW and 343 smaller off-grid projects to bring electricity to remote communities.[6]

SMALL HYDROPOWER SECTOR OVERVIEW

In Mozambique, small hydropower (SHP) is classified as plants with an installed capacity up to 10 MW.[10] In 2017, the total installed capacity of SHP up to 10 MW was at least 4.77 MW, while the total potential capacity of SHP is estimated to be 1,000 MW.[6,11] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019,* installed capacity has increased by 1.4 MW due to new information and the potential capacity has remained the same (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Mozambique (MW)**



Sources: ALER,[6] *WSHPDR 2019,*[11] *WSHPDR 2016,*[12] *WSHPDR 2013*[13]

The country's greatest hydropower potential lies in the Zambezi River basin at sites such as Cahora Bassa North and Mphanda Nkuwa. The overall hydropower potential in the country is estimated to be approximately 19,000 MW.[14] Much of the potential is large hydropower, but at least 5 per cent of it is SHP. Most of the SHP already installed is below 1 MW, with the exception of Pequenos Libombos (1.5 MW) and Cuamba (1.1 MW) (Table 2).[6]

Table 2. **List of Selected Existing Small Hydropower Plants in Mozambique**

Name	*Installed capacity (MW)*	*Operator*
Pequenos Libombos	1.50	IPP
Cuamba	1.10	EDM
Lichinga	0.76	EDM
Rotanda	0.63	FUNAE
Majaua	0.60	FUNAE
Muôha	0.10	FUNAE
Sembezeia	0.06	FUNAE
Chiuraírue	0.02	FUNAE

Source: ALER[6]

SHP plants in Mozambique are particularly concentrated in the centre of the country, more specifically in the Provinces of Manica, Tete and Zambézia. The main players involved in the SHP sector are EDM and the country's Energy Fund, FUNAE. There are additional SHP plants with capacities below 30 kW that were funded and provided technical assistance by the German Corporation for International Cooperation (GIZ) and are operated by local private entities. Some non-governmental organizations including Practical Action and the Association Kwaedza Simukai Manica (AKSM) have also been involved in the funding and execution of other SHP projects.

FUNAE is a publicly owned organization that focuses on small, low-cost power solutions particularly for rural or remote areas. In addition to establishing five SHP plants, the organization also carries out feasibility studies for potential SHP projects with the aim to be invested in by private entities. A feasibility study for a Mavonde SHP project of 0.90 MW was carried out, approved and will begin construction once funds become available. Studies for SHP plants in Berua and Luaice have also been conducted, but no further progress has been announced.[6] SE4ALL, in collaboration with the African Development Bank, has expressed interest in aiding the investment in the creation of green mini-grids to be located in remote areas of Mozambique, which includes power from SHP. An in-depth assessment was made in 2017 that identified hundreds of potential SHP sites in eight provinces with a combined capacity of over 672 MW. These mini-grids along with others from solar power and biomass could bring electricity to 22 per cent of the total population, especially to the hardest to reach communities. To implement these projects, partnerships with international companies, banks and organizations would be necessary.[6]

RENEWABLE ENERGY POLICY

Mozambique is a country rich in natural resources with vast potential for renewable energy including 23,000 MW of solar power, 19,000 MW in hydropower, 4,500 MW of wind power and 2,000 MW of biomass. Harnessing these potentials would not only provide enough energy for the domestic population, but would produce a surplus that could be exported to surrounding countries.[14] Recent national plans routinely mention the development of renewable energy as a priority. The Five Year Plan 2015–2019 discussed the use of renewable energy to obtain other social development goals, such as increasing the electrification rate to 33 per cent by 2019 by increasing hydropower and solar power in rural areas and using solar power to electrify schools and health centres.[6] The actual national electrification rate in 2019 was slightly more than 29 per cent, indicating that this goal was missed by 4 percentage points.[8] The Energy Strategy published in 2015 in conjunction with the World Bank put forth the goal for the national electrification rate to reach 50 per cent by 2023 and 100 per cent by 2030. As of 2020, the country was still 19 percentage points away from reaching the goal in the three following years.

Some of the legal framework for foreign investment and renewable energy is currently undergoing review. The applicable laws presently in place are the Investment Law (Law 3/1993 and Decree 43/2009), Electricity Law (Law 21/1997, Decree 8/2000 and Decree 42/2005), Energy Policy (Resolution 5/1998 and Resolution 10/2009) and Private Public Partnership Law (Law 15/2011 and Decree 12/2012).[11] In 2021, the Government passed regulation framework for off-grid energy production to encourage private sector involvement in installing mini-grids in remote areas in hopes to accelerate electrification of these areas.[15] As of March 2022, the Government proposed, but not yet fully approved, an update of the Electricity Law that would also encourage private investments in the sector and make a more competitive environment.[16] As financial support to make the necessary enabling conditions for private sector investments, Sustainable Energy Fund for Africa (SEFA) approved a USD 740,000 grant in 2015 for technical assistance to do so.[16]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

The National Water Policy (PNA, 1995) stipulates that hydropower installations are required to have a water use concession. In addition, the 1995 policy used two mechanisms for implementation, the Rural Water Transition Plan and the Implementation Manual for Rural Water Projects (MIPAR). In 2007, the PNA was revised and became the Water Policy (PA). The revision was aimed at meeting the United Nations Millennium Development Goals and included private investment in local water management and utilization. The Water Policy mentions the use of water resources for standalone and dam-connected hydropower purposes and states that small- and medium-scale hydropower facilities should be encouraged for off-grid electricity generation in remote areas, extension of the national electricity grid production and transmission capacity, as well as economic development in general.[11]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The challenges hindering the development of SHP in Mozambique include:

- Lack of a consolidated legal framework;
- Absence of a strategy defining governmental investment plans for hydropower plants;
- Limited information about the number and location of the existing plants as well as potential sites;
- Lack of local technologies;
- Underdeveloped market.

The factors encouraging SHP development in Mozambique include:

- Over 995 MW of SHP potential is untapped which offers considerable technical opportunities;
- Access to electricity in the country is still far from universal, especially in rural or remote areas. SHP development in remote areas can bring electricity to communities that have been without;
- Government plans favourable to SHP development.

Réunion

Gaelle Gilboire, Energie Réunion

KEY FACTS

Population	868,846 (2022)[1]
Area	2,512 km^2 [2]
Topography	Réunion island is the result of volcanic activity, with mountain peaks in the interior and two distinct volcanoes: the Piton des Neiges (Snow Peak), which is now extinct, and the Piton de la Fournaise (Furnace Peak), which is younger and more active. The Piton des Neiges is also the highest point on the island at 3,072 metres above sea level.[2]
Climate	In general, the weather in Réunion is tropical and humid. The warm and humid season lasts from November to April, while the drier season occurs from May to October.[3] The summer, which lasts from December to March, has a mean temperature of 26 °C on the coast. Winter, from April to November, has an average temperature of 20 °C on the coast. At higher altitudes, temperatures drop significantly.[2]
Climate Change	Between 1968 and 2021, the average temperature in Réunion rose by 0.18 ° C per decade, or nearly 1 °C in total. By 2100, the average temperature rise is projected to reach 1–3 °C, which will impact the intensity and duration of heat waves and droughts. Between 1961 and 2021, the average rainfall decreased by 1.6 per cent per decade. By 2100, there should be one in five extra rainy days in the wet season and one less rainy day every five days in the dry season. The eastern part of the island will retain much more rainfall than the western part.[4]
Rain Pattern	Summer (January–March) is the wettest season with approximately 200 mm of rainfall per month falling along the coast and up to 1,000 mm in the inland areas. February is usually the wettest month. Annual rainfall exceeds 3,000 mm on the eastern coast and is below 1,000 on the western coast.[5]
Hydrology	A large number of rivers flow through Réunion, including the Rivière des Marsouins that runs abundantly all year round. Other notable rivers are the Sainte Suzanne, Grand-Bois, Salazie and Mafate Rivers.[2]

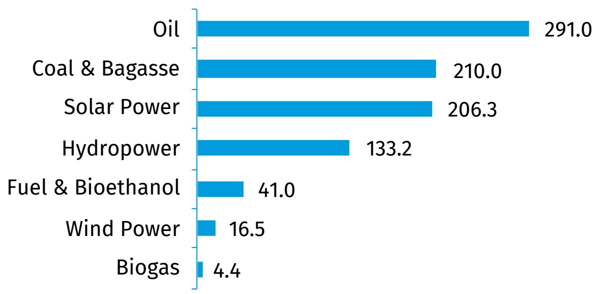
ELECTRICITY SECTOR OVERVIEW

Réunion Island is an overseas department and an administrative region of France. The French company Électricité de France (EDF) is the electricity provider on the island.

In 2020, total electricity generation on the island amounted to 2,978 GWh. Electricity was generated from thermal and renewable energy sources, with coal dominating the generation mix at almost 37 per cent of the total. Renewable energy sources accounted for a total of 31 per cent (Figure 1).[6]

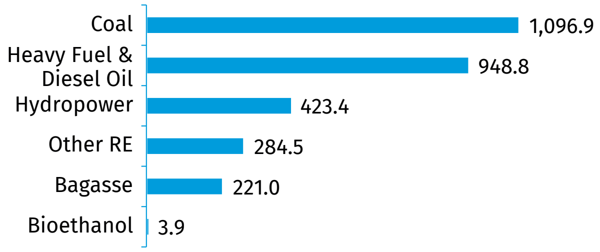
Total installed capacity as of December 2020 was 902.5 MW, of which oil-fired plants accounted for 32 per cent, coal- and bagasse-fired plants for more than 23 per cent, solar power plants for almost 23 per cent, hydropower for 15 per cent, fuel- and bioethanol-fired plants for over 4 per cent, wind power for 2 per cent and biogas for 0.5 per cent (Figure 2).[6] Until 2011, hydropower was the most utilized renewable energy source, as it was one of the first renewable energy sources developed on the island. However, since 2012, Réunion has invested in the development of other renewable energy technologies and now solar power exceeds hydropower in installed capacity.[6] In addition to the listed installed capacities, there is also 6 MW of storage capacity from two batteries.[6]

Figure 1. **Annual Electricity Generation by Source in Réunion in 2020 (GWh)**



Source: Energies Réunion[6]

Figure 2. **Installed Electricity Capacity by Source in Réunion in 2020 (MW)**



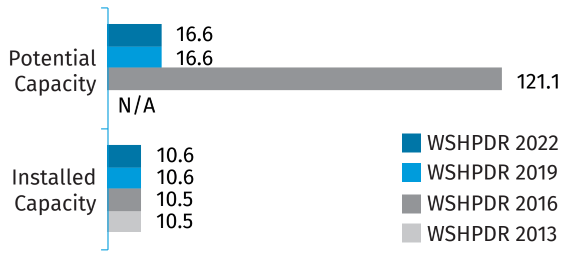
Source: Energies Réunion[6]

Although the cost of producing electricity is higher in Réunion Island due to its insularity, consumers benefit from tariff equalization, meaning that the prices are identical to those in Metropolitan France. Basic electricity tariffs vary according to the voltage and frequency of the electronic devices used as well as the time of the day when they are used. As of 2022, residential tariffs (inclusive of taxes) varied from 0.1371 EUR/kWh (0.14 USD/kWh) to 0.1706 EUR/kWh (0.18 USD/kWh).[7]

SMALL HYDROPOWER SECTOR OVERVIEW

Réunion, in accordance with French legislation, defines small hydropower (SHP) as hydropower plants up to 10 MW. The total SHP installed capacity in Réunion is 10.6 MW (Table 1).[6] The total untapped hydropower potential in the island is estimated at 121.1 MW, of which 59.1 MW is difficult to be developed, 50.5 MW can be developed under strict conditions and 11.5 has no limitations for development.[8] As far as SHP is concerned, the island has 6 MW of untapped potential, making it 17 MW in total.[7] Compared to *the World Small Hydropower Development Report (WSHPDR) 2017*, both installed and potential capacity remained unchanged (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Réunion (MW)**



Source: Energies Réunion,[6] Direction de l'eau,[8] *WSHPDR 2013*,[9] *WSHPDR 2016*,[10] *WSHPDR 2019*[11]

Hydropower on the island is produced at Rivière de l'Est (79.2 MW), Takamaka I (17.4 MW) and II (26.0 MW), Bras de la Plaine (4.6 MW), Langevin (3.6 MW), Bras des Lianes (2.2 MW), Ligne Paradis (0.2 MW) and RT4 (0.02 MW) plants, for a combined capacity of 133.2 MW.[6] Although a large share of the SHP potential has been tapped, there are still a number of potential sites where micro-hydropower projects can be developed (Tables 2 and 3).[14]

RENEWABLE ENERGY POLICY

Act No. 2015-992, Article 1, of 17 August 2015 lays down the guidelines for energy policies and renewable energy for French overseas departments.[13] The law states that overseas departments should be energy-autonomous by 2030, with an intermediate goal of 50 per cent of renewable energy in the energy mix by 2020. In addition, incentive mechanisms are also in place to encourage the development of renewable energy, including tax exemptions, direct subsidies and feed-in tariffs (FITs) controlled by EDF.

In 2017, in the Multiannual Energy Programme (PPE) the Regional Council of Réunion Island and the Government of France defined the energy policy until 2023 for the island. The PPE set the development objectives for each renewable energy source for the period from 2018 to 2023 in order to achieve energy autonomy by 2030. The programme takes into account population and electricity consumption growth, with objectives focusing on demand-side management as well. In this document, the objective for hydropower is to add 39.5 MW of capacity between 2016 and 2023. However, the project of a new 39 MW turbine on which this objective was based will not be realised.[14]

In April 2022, an updated version of the PPE was adopted with new objectives set for 2023 and 2028. These include reducing electricity consumption by 263 GWh/year by 2023 and 438 GWh/year by 2028 as well as stopping using coal and heavy fuel oil for electricity generation. The two existing carbon-fired power plants will be converted to the use of biomass. The new objectives defined for hydropower are to add 6.6 MW of capacity by 2023 and another 1 MW by 2028, indicating a reduced focus on hydropower in the new edition of the PPE in favour of other renewable energy sources.[12]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The main barriers to SHP development include:

- Costly technology due to the insularity of the island and the related costs of transportation and taxes, which limits contractors' willingness to undertake financial risks and invest in Réunion;
- Climatic variations and destruction coupled with volcanic activity are other risk variables of the island that investors and contractors need to face;
- Réunion is classified by the United Nations Educational, Scientific and Cultural Organization (UNESCO) as a World Heritage Site, which has two main consequences: first, environmental impact assessments are stringent; and second, the price of land per square metre has experienced a significant increase, affecting initial investment expenditures;
- Ineffective coordination between local and overseas authorities prolongs the implementation process for project owners;
- Lack of local technical support;
- Lack of information and contradictory sources, slowing down the process of development.

On the other hand, the key enablers include:

- Availability of undeveloped SHP potential;
- Policy support of renewable energy;
- Availability of irrigation and water treatment infrastructure on which SHP plants could be installed.

Rwanda

Davy Rutajoga, International Center on Small Hydro Power (ICSHP)

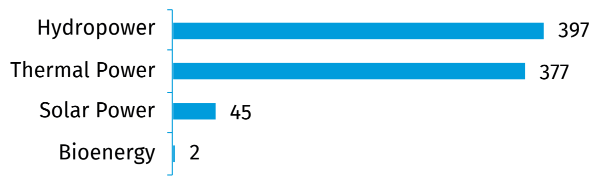
KEY FACTS

Population	12,955,736 (2021)[1]
Area	26,338 km^2 [2]
Topography	Rwanda is a landlocked country that lies 120 kilometres south of the equator in the Tropic of Capricorn. Rugged with steep hills and deep valleys, the altitude ranges from approximately 1,000 metres above sea level in the east to the 4,507 metre peak of Mount Karisimbi in the Virunga Volcano Range in the west of the country.[2,3]
Climate	Rwanda has a temperate tropical highland climate characteristic of high-altitude regions in the equatorial belt. Average annual temperatures range between 23 °C and 24 °C in lowlands and reach up to 17 °C in high altitude areas. Generally, temperatures vary little throughout the year.[4]
Climate Change	As a country that relies heavily on rain-fed agriculture, Rwanda is highly vulnerable to rising temperatures as well as the irregular rainfall patterns that have been projected to increase in the future. Increases in temperature of between 1.4 °C and 2.6 °C have been observed in the south-western and eastern regions of the country between 1971 and 2016. Precipitation also exhibited noticeable variations, with mean rainfall decreasing significantly in January, February, May and June and increasing significantly from September to December. Climate projections for the high-emissions scenario estimate an annual mean temperature increase of 1.1 °C between 2020 and 2039, 1.9 °C between 2040 and 2059, 2.9 °C between 2060 and 2079 and 3.9 °C between 2080 and 2099. Annual precipitation is also likely to increase, with a higher intensity of heavy rainfall. These variations in temperature and precipitation are projected to also impact water resources, which could in turn impact the energy sector.[5]
Rain Pattern	Rwanda experiences relatively abundant rainfall through its two rainy seasons: the long rainy season (March to May) and the short rainy season (September to November). The eastern plains enjoy an annual rainfall of between 700 mm and 1,100 mm, the central plateau of between 1,100 mm and 1,300 mm and the highlands of between 1,300 mm and 1,600 mm. The areas around the town of Bugarama and Lake Kivu benefit from an annual rainfall of between 1,200 mm and 1,500 mm. The mean annual precipitation in the country is 1,177.7 mm.[5]
Hydrology	Located in the Great Lakes region of Africa, Rwanda has 101 lakes split into two basins: the Nile basin to the east and the Congo basin to the west. The country's hydrological network covers approximately 8 per cent of the national territory, with 10 per cent of the water draining into the Congo basin. The largest lake in Rwanda is Lake Kivu, a methane-rich lake shared with the Democratic Republic of the Congo.[5]

ELECTRICITY SECTOR OVERVIEW

The electricity supply in Rwanda is made up of domestic generation and electricity imported from neighbouring countries and regional shared power plants.[6] The main sources of electricity in Rwanda are hydropower, thermal power (diesel and methane) and solar power accounting for approximately 48 per cent, 46 per cent and 6 per cent, respectively, of total production, which amounted to 821 GWh in 2019 (Figure 1). Renewable energy contributed a combined 54 per cent of the electricity generated.[7]

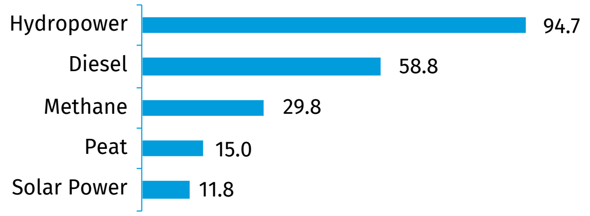
Figure 1. **Annual Electricity Generation by Source in Rwanda in 2019 (GWh)**



Source: IRENA[7]

The total installed capacity in 2020 was 210.1 MW, of which approximately 45 per cent came from hydropower, 49 per cent from thermal power (diesel, methane, peat) and 6 per cent from solar power (Figure 2). Thermal power is only used during peak hours due to the high operating costs associated, with hydropower taking over during off-peak hours as a cheaper option. Additionally, Rwanda imports electricity from the National Electricity Company of Congo (SNEL) and the Uganda Electricity Transmission Company (UETCL).[8]

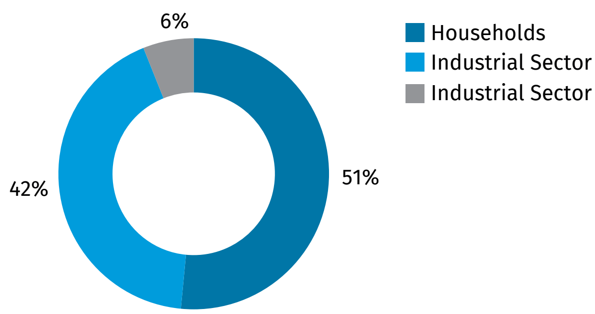
Figure 2. **Installed Electricity Capacity by Source in Rwanda in 2020 (MW)**



Source: REG[8]

In Rwanda, the dominant consumers of electricity are households, followed by industries and the public sector, with consumption rates of approximately 51 per cent, 42 per cent and 6 per cent, respectively (Figure 3). The per capita consumption rate is expected to increase to 3,080 kWh in 2050 from 50 kWh in 2019, with at least 60 per cent of the electricity to be generated from renewable energy sources under the Vision 2050 strategic plan for the transformation and modernization of the country.[5]

Figure 3. **Electricity Consumption by Sector in Rwanda (%)**



Source: World Bank[5]

Electricity in Rwanda is distributed by the Rwanda Energy Group (REG), a Government-owned corporation which oversees all energy development and investment plans in the country under the auspices of the Ministry of Infrastructure (MININFRA). Private entities can purchase, build and operate power plants in Rwanda, but the distribution is handled by the REG. As of 2021, the cumulative connectivity rate was 67 per cent of Rwandan households, including approximately 49 per cent connected through the national grid and 19 per cent accessing through off-grid systems (primarily solar power). An electricity access target of 100 per cent of households by 2024 with 69 per cent connected through the grid and 31 per cent off-grid has been set by the Government.[9]

Electricity tariffs are established by the REG and are based on flat rates and smart meters that measure levels of electricity consumption. The electricity tariffs for the main groups of consumers are listed in Table 1.

Table 1. **Average Electricity Tariffs in Rwanda**

Type of consumer	*Type of rate*	*Average electricity tariff (USD/kWh)*
Residential	Smart meter	0.089–0.245
Commercial	Smart meter	0.157–0.201
Industrial	Flat rate	0.106–0.151
Industrial 2	Smart meter	0.094–0.134
Public sector	Smart meter	0.126

Source: REG[10]

Based on a study conducted by Israel Electric on the current and forecasted electricity demand in Rwanda for the years 2016–2040, an average of a 10 per cent annual demand growth rate has been estimated.[8] As part of the Vision 2050 plan, the development of electricity connectivity focuses on hydropower as the area with the most potential to meet the demand due to the abundance of water resources in the country and region.[5]

SMALL HYDROPOWER SECTOR OVERVIEW

Small hydropower (SHP) plants in Rwanda are defined as plants with an installed capacity of up to 5 MW. There were 29 SHP plants operating in Rwanda in 2020 out of 333 identified potential sites, with a total installed capacity of 34.4 MW and an available capacity of 18.66 MW.[8] The total theoretical SHP potential capacity in Rwanda is estimated to be 111.1 MW (based on planned projects and identified sites).[11] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, the SHP installed capacity increased as a result of the commissioning of new plants, whereas the potential estimate remained unchanged (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Rwanda (MW)**

In addition to the existing SHP plants, a further 10 SHP plants are planned in Rwanda, with some expected to start commercial operation between 2022 and 2024 (Table 3). The total nominal capacity of the planned SHP plants with an individual capacity of less than 5 MW is 32.8 MW and the nominal capacity of all planned plants up to 10 MW is 52.4 MW.[8]

MININFRA commissioned a study to identify potential hydropower sites, which was carried out in 2006-2007 by SHER ingénieur-conseil, a Belgian-based company funded by the Belgian Development Corporation. Through this study, a hydropower atlas highlighting the different potential areas for hydropower development was developed. Each identified site was classified based on its potential capacity, from pico-hydropower sites (up to 5 kW) to larger sites with more than 1 MW of capacity. Almost 50 per cent of the potential sites were found to be in the range of 5–100 kW. The theoretical hydropower potential capacity identified in the study totalled 82.6 MW, including 61.2 MW at already equipped or soon-to-be equipped sites.[8]

RENEWABLE ENERGY POLICY

The renewable energy sector is led by the Rwanda Energy Policy (REP), established as a guiding framework for the sector in 2015, following Law No. 21/2011 of 23 June 2011 governing electricity in Rwanda. Under the REP, the Rwanda Utilities Regulatory Authority (RURA) is mandated to regulate the supply of sufficient, reliable, affordable and sustainable energy to all customers. This supply follows the targets set for renewable energy by the Energy Sector Strategic Plan for 2018/19–2023/24, which guides the implementation of the REP.[14]

As part of the Vision 2050 plan, Rwanda is putting climate resilience and a low-carbon economy at the heart of its development. To this end, the share of renewable energy in the country's generation mix is targeted to reach at least 60 per cent by 2035.[5] SHP is an integral part of the country's effort towards achieving this goal, with sustainable small-scale generation installations in rural areas being a key component of the Green Growth and Climate Resilience Strategy of Rwanda. This strategy is highlighted in the country's Nationally Determined Contribution (NDC), with the increased use of hydropower (both large and small) representing the largest share of the identified greenhouse gas (GHG) mitigation potential.[15]

As part of the country's effort to promote SHP, a feed-in tariff (FIT) scheme was introduced between 2012 and 2015 by the Energy, Water and Sanitation Authority (EWSA) in close collaboration with the RURA. The scheme covered hydropower plants ranging in capacity from 50 kW up to 10 MW and located within 10 kilometres from the transmission network (Table 4). Although the policy expired after a duration of three years and has now been replaced by renewable energy tenders, this does not affect the projects that signed power purchase agreements (PPAs) under the scheme during that period.[16]

Table 4. **Small Hydropower Feed-in Tariffs in Rwanda**

Plant installed capacity (MW)	*Feed-in tariff (USD/kWh)*
0.05	0.166
0.10	0.161

Source: RURA[16]

Rwanda is a signatory to the United Nations Sustainable Energy for All Initiative (SE4ALL) and the Regional Strategy on Scaling up Access to Modern Energy Services adopted by the Council of Ministers of the East African Community. As such, the country adopted policies to create an environment that enables off-grid energy service provision including the development of small-scale renewable energy solutions.[16]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

SHP plants are regulated by some of the same legislation as larger hydropower projects. The main legislation and regulation documents in Rwanda concerning hydropower are:

- The National Energy Plan (2015);
- Regulations No.001/ENERGY/RURA/2012 Of 09/02/2012 On Rwanda Renewable Energy Feed-In Tariff (2012);
- Guidelines No.02/GL/EL-EWS/RURA/2019 On Minimum Technical Requirements for Mini-Grids in Rwanda (2019).

Any energy generation project in Rwanda, including SHP plants, is required to receive a generation licence from the Rwanda Utility Regulatory Authority (RURA), with the fee depending on the planned capacity of the project (Table 5).

Table 5. **Electricity Generation Licence Fees in Rwanda**

Capacity	*Fee (USD)*
Less than 0.5 MW	5,000
0.5–1 MW	10,000
1–5 MW	15, 000

Source: RDB[17]

In addition to the generation licence fee, a licence application fee of USD 500 is to be paid.[17] As part of the application, the following documents have to be filed:

- Application letter addressed to the RURA Director General;
- Original receipt of the application fee payment;
- Domestic company registration certificate from the Rural Development Board (RDB);
- Business plan;
- Copy of the feasibility study of the project;
- Environmental Impact Assessment Certificate;
- Memorandum of understanding/Concession agreement between the Republic of Rwanda and the applicant;
- Power purchase agreement (not applicable to provisional licence);
- District authorization approving planned activities;
- Copies of applicant's financial statements audited by an independent auditor for the previous three years for the existing companies and the initial balance sheet for newly formed companies;
- Other relevant information detailed in the Electricity Licensing Regulations depending on the type of licence applied for.[17]

All licensing of power plants in Rwanda is acquired through the RDB, which oversees development projects in the country. The RDB is open to investors who wish to invest in SHP projects and has a directory of potential SHP sites and projects to accommodate investors. Most SHP projects are Government-funded through the RDB and the REG, with the remaining projects owned by companies and IPPs.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

With Rwanda depending on hydropower for most of its electricity generation, the effects of climate change are likely to significantly affect the energy sector in the country. Indeed, variations in rainfall patterns have already been observed and changes in mean temperature are predicted to occur, threatening water storage and supply.[5] In addition, hydropower is also vulnerable to the increased risk of damage to infrastructure, including roads, dams, turbines and supply lines, caused by floods. On the other hand, increased rainfall could also present an opportunity for SHP development as it would increase generation capacity at potential sites, which would bring the country closer to its goal of 60 per cent share of renewable sources in the generation mix by 2035.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Though SHP development presents an opportunity for Rwanda to reach its target energy goals, there are factors that hinder that development, such as:

- High costs associated with construction due to the relatively complex design of SHP plants, which require significant custom engineering. With few manufacturers to purchase from, the prices of building equipment are relatively high;
- Rwanda does not manufacture the necessary equipment for SHP plants and has to import them from outside of Africa, with import costs being relatively high due to the lack of a sea port in the country;
- The siltation as a result of the erosions caused by the hilly topography of the country and human activity (e.g., agriculture);
- The water levels drop by approximately 30 per cent during dry seasons, which affects generation by SHP plants;
- The mountainous topography of the country makes transmission and distribution relatively expensive.[18,19]

Enablers for further SHP development in Rwanda are:

- The availability of undeveloped potential SHP sites, which, due to their distributed nature, might be complimentary to micro-grids to provide 24/7 generation in combination with solar photovoltaic (PV) installations;
- Domestic production of electricity eliminates the need for foreign currency used for imports;
- Most potential SHP sites identified are suitable for development using run-of-river methods, which do not require large dams to impound water and, hence, are less environmentally challenging and more cost-effective;
- The Government's strategy to transition to a climate-resilient and low-carbon model of development specifically highlights the need for small-scale renewable energy production.

Somalia (Federal Republic of)

Victor Odundo Owuor, One Earth Future Foundation

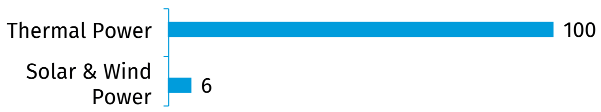
KEY FACTS

Population	15,442,905 (est. 2019)[1]
Area	627,340 km^2 [2]
Topography	Located in the Horn of Africa, Somalia boasts the longest coastline of any country in the continent. In the north, higher plateaus and mountains reach between 900 and 2,100 metres above sea level, gradually declining into a central plateau. In the south, the region transitions into lower coastal plains and fertile agricultural areas between the Jubba and Shabelle Rivers, before extending into low pastureland on the border with Kenya.[3]
Climate	Somalia has a semi-arid to arid climate, which is determined by its location in the Intertropical Convergence Zone.[4] Temperatures range between 20 °C to 40 °C in the south with cooler temperatures along the coast and reach as high as 45 °C in the northern coastal plains.[5]
Climate Change	Since 1991, the median annual temperature in Somalia has increased by 1–1.5 °C. Climate change projections predict that median annual temperatures will further increase by another 3.4–4.3 °C by the year 2100. Extreme weather phenomena are becoming more common and harder to predict. While a slight increase in rainfall of approximately 3 per cent is predicted by 2050, an increase in droughts and dust storms has also been observed. Additionally, the changing global and regional weather patterns have led to massive locust invasions in the Horn of Africa, costing Somalia approximately 20 per cent of national crop yields in 2020.[6,7]
Rain Pattern	The major wet season (*Gu*) lasts from April to June, followed by the *Haggai* season, which brings relatively cool temperatures with drier conditions on the inland plateau and light showers along the coast.[8] The *Deyr* rains occur from October through November, which lead into the longer dry *Jilaal* season spanning from December through March. Precipitation levels range from 700–800 mm/year in the Jubba and Shabelle regions to less than 100 mm/year along the northern coast.[4]
Hydrology	The majority of the country's water resources are dominated by surface water obtained from the Jubba and Shabelle Rivers, with 90 per cent of flows originating in the Ethiopian Highlands. Total internal water resources, including both surface and ground water, average 6 km^3/yr.[3]

ELECTRICITY SECTOR OVERVIEW

As of 2020, the installed electricity capacity of Somalia was estimated at 106 MW, down from an estimated historical capacity of 175–180 MW prior to the outbreak of the civil war in the early 1990s. The majority of the country's electricity is supplied by fossil fuel-based thermal generators (100.0–103.4 MW), with some renewable energy generated through solar and wind power (2.6–6.0 MW) (Figure 1).[3,9,10] Within the energy sector as a whole, as much as 80 to 90 per cent of energy originates from biomass sources, with the greatest share represented by charcoal. Fossil fuel usage accounts for 10 per cent of the energy mix, of which diesel-powered generators represent approximately 2 per cent.[9,10]

Figure 1. **Installed Electricity Capacity by Source in Somalia in 2020 (MW)**



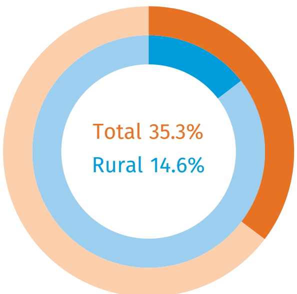
Source: AfDB,[3] USAID[9]

The decades' long civil war has undermined and destroyed much of the energy sector of Somalia. The combination of the protracted conflict and subsequent statelessness has significantly reduced the country's electrical generation capacity, namely through the destruction of electrical grids and by allowing infrastructure to fall into disrepair. Perhaps just as damaging was the effect that the war had on reducing international investment, the availability of a skilled workforce and Government regulatory oversight. In recent years, an added element of concern is the security risk that Al Shabaab and other armed militia groups pose to any large-scale infrastructure projects due to the potential for inflicting significant damage to the country's economic system.[11]

Precise and reliable data relating to installed capacity and electricity generation is difficult to obtain due to the fragmented nature of the energy sector and the sparse availability of data. The World Bank reported that 29.9 per cent of the population has access to electricity in 2016, which translated into an estimated 270,000–679,073 individual connections to households and businesses, while the most recent World Bank estimate indicates a 35.3 per cent electricity access rate in 2018 (Figure 2).[11,12] Other recent estimates put electricity access at as low as 16 per cent of the total population.[9] In terms of overall electricity consumption, estimates indicate that Somalis rank in the bottom 1 per cent of the world average at 28.7 kWh per capita and that some 2.4 million households do not have electrical power.[11]

These numbers do not reflect the vast disparity that exists between rural and urban populations' access to electricity. Electrification in rural areas is limited or non-existent due to the lack of infrastructure and connections to a larger electrical grid structure.[11] However, it should be noted that rural electricity access has shown gradual improvement with the added accessibility and convenience of solar photovoltaics (PV) technology, which has allowed some households and businesses to access electricity on a smaller, individual scale. Urban electrification varies by city and region, depending on the level of infrastructure and the generating capacity of privately owned electrical companies.[3] For example, estimates of electricity access in Mogadishu and Somaliland have reached as high as 60 to 70 per cent, whereas smaller cities, such as Merka, only have 23 per cent access.[13] The latest World bank estimates suggest a 60.5 per cent electricity access in urban areas, but only 14.6 per cent access in rural areas.[12]

Figure 2. **Electrification Rate in Somalia in 2018 (%)**



Source: World Bank[12]

As a result of the weakened state of the Somalian public energy sector, the private sector has taken a primary role in sourcing and providing electricity. Rather than through large, centralized systems of power generation, the majority of electricity in Somalia is generated by small independent providers operating through local or regional companies.[14] Without the Government oversight, these independent power companies have improvised their own local systems of electricity distribution, but lack a coherent interconnected grid between generators that could promote more efficient and cost-effective economies of scale.[11] In addition to these independent networks, there is also a smaller subset of semi-public utility companies that provide electricity to large urban areas, but they operate on dated grid systems and are only present in selected cities, including Hargeisa, Qardo, Berbera and Bosaso.[3]

While the flexible and adaptive nature of the private sector energy companies has its advantages, including access to private funding sources in the Somali diaspora and fast mobilization, they also have distinct weaknesses. The radial system of individual electrical networks is characterized by medium- to low-tension power supplies, which are further diminished by transmission losses of up to 50 per cent of starting power levels. Compared to other African countries or even other fragile and conflict-affected countries, this is four and two times higher than the average rate of losses, respectively.[3] This means that, on average, voltage rates are typically 220–400 V, but are often as low as 150–220 V. As a result, most households with access only use electricity for lighting purposes or other low current appliances.

The national and regional Governments are responsible for overseeing and implementing the energy sector policy. In 2010, the Ministry of Mining, Energy and Water Resources of Somaliland passed an Energy Policy that initiated a regulatory framework for the region. In conjunction with the Energy Policy, Somaliland has made multiple attempts to pass an Electrical Energy Act, which would establish a formal legal framework overseeing tariff rates, administration and skilled training initiatives; however, the Act has not been adopted as of 2021.[15] Overall, no legislation has been passed at the federal level that specifically addresses the electricity industry. However, in 2016 the Government partnered with the African Development Bank Group to complete an Energy Sector Needs Assessment, which laid out multiple strategies aimed towards expanding the electrical capacity of Somalia. One such strategy calls for increasing the supply of electricity to regional capitals through hybrid mini-grids, implying close to 200 MW of additional generating capacity over a 10-year period.[3] To date, the Government does not have the necessary staff or budget to initiate such projects and requires international donor support to accomplish its large-scale energy infrastructure goals.

This lack of regulation and oversight extends into the affordability of electricity as well. With average rates between 0.80 and 1.20 USD/kWh (Table 1), the electricity tariffs in Somalia rank among the highest in the world, especially when considering that the GDP per capita in 2017 was USD 434.21.[3,12] Most power companies do not have a formal metering system and instead charge by the number of light bulbs or the number of appliances powered within a household or business. Some independent providers have even utilized tiered rates, meaning that some public and private institutions like mosques or government facilities pay a lower rate as compared to other consumers or nothing at all.

Table 1. **Electricity Tariffs in Somalia**

Tariff type	*Price (USD/kWh)*
Nationwide average	0.80–1.20
Single-phase supply	0.60–1.20
Three-phase supply	0.65–0.80

Source: AfDB,[3] REEEP[13]

Regional variation in price is largely dependent upon the energy provider, the level of available infrastructure and the consumer's proximity to urban centres or the primary electricity generation source. In order to supplement its energy needs and to offset high tariffs, Somalia has tapped into power surpluses in neighbouring countries. In 2014, the Federal Government entered into a shared understanding with Kenya and Ethiopia to build a hydropower plant on their shared border on the Dawa River and has worked with Ethiopia to connect to its grid system in areas along the Somaliland border as well as in Puntland.[3] In the long term, there has also been discussion around utilizing the Eastern African Power Pool (EAPP) as a potential source of electric power, but the current load and lack of interconnection in Somalia suggest limited benefits for the required cost.[11]

SMALL HYDROPOWER SECTOR OVERVIEW

Somalia has no official definition for small hydropower (SHP). This chapter adopts the working definition of hydropower plants with an installed capacity of up to 10 MW. Currently there are no operational hydropower plants in the country; however, there is some potential to rehabilitate plants that were in place prior to the civil war. The current state of SHP does not reflect the historical development and use of hydropower in Somalia. Though it has fallen into disrepair, the Fanoole hydropower dam was completed in 1982 in partnership with China. The plant was designed to generate electricity for local communities in Jilil and Marere and to support an agricultural programme focused on sugar cane and rice irrigation.[16] In their 2016 Intended Nationally Determined Contributions (INDC) report, the Somali Federal Government announced plans to rehabilitate the dam's hydropower infrastructure for an estimated USD 28 million.[16] If completed, the refurbished plant would restore 4.6 MW of power as well as re-establish two standby generators with a capacity of 1,600 kW. This dam has the potential to reinvigorate the agricultural sector in the Middle and Lower Jubba Valley, but the project includes extensive repairs and rechannelling the path of the river which was diverted during the 1998 El Niño rainy season. The SHP potential of Somalia is unknown and is based only on known planned projects. Somalia remains a very challenged jurisdiction and no changes have occurred in its SHP sector since the *World Small Hydropower Development Report (WSHPDR) 2019* (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2019/2022 in Somalia (MW)**

Source: AfDB,[3] REEEP,[13] *WSHPDR 2019*[17]

Note: Somalia was not covered in *WSHPDR 2013* and *WSHPDR 2016*.

Relative to the abundance of hydropower generation in Ethiopia, Somalia has a much more limited capacity. The country has an estimated economic potential capacity of 100–120 MW of total hydropower, which is concentrated along the Shabelle and Juba Rivers in the south.[3,11] Historically, there were also plans to construct the Bardheere plant upstream of the Fanoole plant with a capacity of 493 MW, but the civil war effectively halted the project.[16] This reflects many of the challenges faced by Somalia in initiating SHP projects, namely the lack of financing from the Government and international donors, the current unpredictable weather patterns affecting Eastern Africa, concentration of already scarce resources to combat the COVID-19 pandemic and the high degree of terrorist activity conducted by Al Shabaab in the region.

RENEWABLE ENERGY POLICY

As mentioned, charcoal currently represents the most cost effective and accessible energy source in Somalia. However, the proliferation of charcoal consumption and its export to international markets in the Middle East has resulted in widespread deforestation, environmental degradation and negative health outcomes. The rising cost of charcoal (which sits at approximately 50 per cent of household incomes) and the vast potential for solar and wind power generation have driven the Federal and regional Governments to integrate renewable energy into their development plans and policies (Table 2).[3]

Table 2. **Renewable Energy Potentials in Somalia**

Type	*Potential*	*Location/Region*
Solar power	200 kW/km²	Coastal south-central Somalia
Wind power	30–45 GWh/km²	Puntland and Somaliland
Hydropower	100–120 MW	Juba and Shabelle River region

Source: Federal Government of Somalia,[10] REEEP[13]

Given the lack of any regulatory frameworks, renewable energy has been integrated into the larger discussion and the legislative push towards formal energy policy in Somalia. The different regional Governments have committed to a number of energy and renewable energy policy objectives (Table 3).

Table 3. **Energy Policies in Somalia**

Source	*Year*	*Policy*	*Objective*
Federal Government of Somalia	2014	2014–2015 Economic Recovery Plan	Incorporated provisions for renewable energy integration
	2016	2017–2019 National Development Plan	Sustainable Energy Investment Policy and Energy Strategy provision
Somaliland Ministry of Energy and Mining	2010	Somaliland Energy Policy	Promotion of renewable energy technologies and reduction of taxes and duties on importing renewable equipment;
			Increased budget allocation to ministries overseeing renewable energy activities;
			Infrastructure resources (i.e., transportation and communications) to help administrators implement and monitor renewable energy–related activities;
			To develop and sustain efficient use of renewable energy resources as part of the energy mix, in ways that increase affordable access in urban and rural areas.
Puntland	2013	2014–2016 Puntland Government Plan	Identified renewable energy as one of four key priorities for the economy;
			Set a target of a 20 per cent increase in solar and wind power generation and usage over a five-year period.

Source: Federal Government of Somalia,[10] One Earth Future,[11] REEEP,[13] Watanabe & D'Aoust[14]

COST OF SMALL HYDROPOWER DEVELOPMENT

There is very little data on the cost of potential SHP projects in Somalia now or in the future. However, a partial estimate of the costs of the refurbishment of the Fanoole plant is provided in Table 4.

Table 4. **Cost of the Refurbishment of the Fanoole Hydropower Plant**

Project component	*Cost (USD million)*
Initial cost of construction (1977–1982)	50.0
Refurbishment of dam and electrical facilities	17.0
Rehabilitation of canals and river channel	2.0
Rebuilding of offices, residential buildings and connected agricultural facilities	5.5
Contingency and administrative costs	3.7
Total (refurbishment)	**28.2**

Source: Federal Government of Somalia[16]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

As there is no current or projected SHP development in Somalia, it is difficult to gauge the possible impacts of climate change on its trajectory. While some increase in rainfall is expected over the next 30 years, precipitation and, thus, runoff are also likely to become less predictable and experience greater variation. However, the main aspect of climate change that is adversely affecting the prospects of SHP development in Somalia are the climate change impacts on the local population, including:

- Drought and land degradation undermining agricultural and pastoral livelihoods;
- Extreme weather displacing populations from affected regions;
- Increased confrontation between communities over dwindling resources.

These factors have led to continued social, political and economic instability in Somalia and have effectively made any kind of large-scale construction impossible in many parts of the country, particularly in the Shebelle and Juba River basins where much of the country's SHP potential is located.[7]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The key challenges that Somalia faces in developing SHP are as follows:

- Security concerns surrounding regional terrorist groups, such as Al Shabaab, and the potential for SHP infrastructure and energy grids to be targeted or attacked;
- Limited regulation and oversight of the electricity sector;
- Lack of field studies for SHP potential;
- Low domestic resource mobilization coupled with on-going efforts to combat the COVID-19 pandemic have deepened fiscal pressures;
- Limited Government capacity to administer and regulate the energy sector;
- Lack of a skilled workforce to design, build and maintain SHP and renewable energy infrastructure due to the protracted conflict;
- Absence of an interconnected grid system with high enough capacity to support transmission and usage of electricity for both urban and rural populations;
- Aging equipment and poor infrastructure in thermal generation, which contributes to up to 50 per cent of electricity loss;
- Scarcity of private sector financing for renewable energy projects and materials;
- Limited interconnection with regional power pools, particularly those in Ethiopia and Kenya;
- Low donor support for large-scale government projects, including those for rehabilitating SHP plants in poor condition and initiating a mini-grid system in key urban areas.

The main prospect for SHP development in Somalia remains the refurbishment of the Fanoole plant on the Juba River. The plant's infrastructure is still largely intact and preliminary plans for proposed works were drawn up in 2015. Refurbishment of the plant, if completed, is expected to have a major positive impact on local agricultural productivity.

South Sudan

International Center on Small Hydro Power

KEY FACTS

Population	11,381,377 (2020)[1]
Area	633,907 km^2 [2]
Topography	South Sudan mostly consists of mountains, plains and plateaus. The central region is relatively flat and has multiple swamps, while the peripheral areas are higher in elevation. Near the southern border with Uganda lies the Imatong Mountain Range, home to the country's highest peak, Mount Kinyeti, which culminates at 3,187 metres.[3]
Climate	South Sudan has a tropical climate. Temperatures are generally high at an average of 25 °C, often exceeding 35 °C in the dry season (January-April). In the centrally-located capital city of Juba, temperatures reach an average high of 34.5 °C and an average low of 21.6 °C.[4]
Climate Change	South Sudan is affected by global warming. In recent years, the frequency and intensity of extreme climatic events has increased, including floods and droughts. Heatwaves and droughts have also been reported. Since the mid-1970s, the country has experienced a 10–20 per cent decrease in long rains. The agricultural areas, usually receiving the most rainfall in South Sudan, have experienced an 18 per cent decrease in precipitation. This country-wide decrease in precipitation is projected to reach a peak decrease, between 2010 and 2039, of 150 mm between June and September. Average temperatures in the country are projected to increase by 0.6-1.7 °C by 2030 and by 1.1-3.1 °C by 2060.[5]
Rain Pattern	South Sudan experiences a rainy season from April to November, although this can vary from region to region. The lowland areas of Jonglei, Bahr El Ghazal, Eastern Equatoria and the Upper Nile receive annual precipitations between 700 mm and 1,300 mm. However, the southern tip of Eastern Equatoria receives less rainfall (approximately 200 mm). The southern upland areas receive the most rain and the northern areas the least. Western Equatoria receives between 1,200 mm and 2,200 mm of precipitation annually.[4]
Hydrology	The hydrological landscape of South Sudan is dominated by the Nile River system, which runs from south to north and is joined by its tributaries: the Bahr Al-Arab, Sobat and Bahr El Ghazal. A large swampy area, the Sudd wetland, occupies the centre of the country and is one of the largest freshwater ecosystems in the world. It incorporates an area of about 57,000 km^2.[5]

ELECTRICITY SECTOR OVERVIEW

Due to the status of South Sudan as the newest nation in Africa, which it became after gaining independence in 2011, the electricity sector in the country is still undeveloped. The transmission system has not been updated nor has the country's renewable energy potential been exploited. The main source of electricity in South Sudan is thermal power, which accounted for 580 GWh, or 99.8 per cent, of the total electricity generation of 581 GWh in 2019 (Figure 1). Solar power accounted for 0.2 per cent, or 1 GWh, of the total electricity generated that year.[6]

Due to the country's history of civil war and its relatively recent cessation from Sudan, little electrical infrastructure has been built. There is no extensive electricity grid in the country and most businesses and individuals rely on their own diesel-powered generators for electricity. The total installed electricity capacity in South Sudan in 2020 was 175 MW, with thermal power and solar power accounting for approximately 99.4 per cent and 0.6 per cent, respectively (Figure 2).

Figure 1. **Annual Electricity Generation by Sources in South Sudan in 2019 (GWh)**

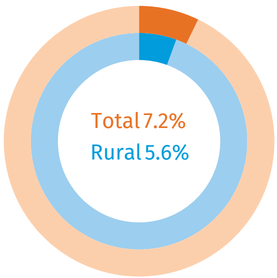
Source: IRENA[6]

Figure 2. **Installed Electricity Capacity by Source in South Sudan in 2020 (MW)**

Source: IRENA[6]

Due to the lack of an extensive electricity grid and overall electricity infrastructure, South Sudan has the lowest rate of electrification in the world. The total electrification rate in the country was 7 in 2020, with less than 6 per cent rate of access in rural areas (Figure 3).[7,8]

Figure 3. **Electrification Rate in South Sudan in 2020 (%)**



Source: World Bank[7,8]

South Sudan is endowed with considerable natural resources, including crude oil and natural gas. Crude oil exports form the backbone of the country's economy, with Sudan being one of the main importers.

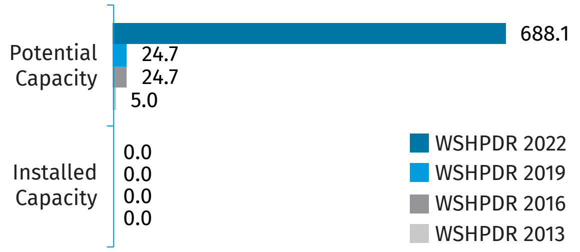
The South Sudan Electricity Corporation (SSEC) is the only electricity utility in the country and is mandated with the production, distribution and supply of electricity. It is overseen by the Ministry of Electricity, Dams, Irrigation and Water Resources. The SSEC has also undertaken the task of overseeing the rehabilitation of the few power plants damaged during the civil war through partnerships with other countries, particularly China. This partnership with China has also resulted in the construction of 33 kV transmission lines that are to supply 20,000 customers with electricity, as well as the production of 13,450 prestressed concrete poles for power plants that are being built for the purpose of creating an extensive national grid and establishing interconnections with neighbouring countries. A loan of USD 14.6 million from the African Development Bank has been approved for the grid project, supplementing the initial loan of USD 26 million issued in 2013. The new loan was approved in 2017 and construction began in 2018.[9]

Electricity tariffs in South Sudan were set in 2014 and reviewed in 2017 to reach an average of 0.43 USD/kWh.[10]

SMALL HYDROPOWER SECTOR OVERVIEW

South Sudan does not have an official definition of small hydropower (SHP). Despite abundant natural resources and considerable hydropower potential, there are no SHP plants in the country. There is an estimated SHP potential of 688.1 MW that is yet to be exploited.[11] This is a 2,686 per cent increase from the estimated SHP potential in the *World Small Hydropower Development Report (WSHPDR) 2019* and is based on a more recent study of SHP potential in Sub-Saharan Africa (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in South Sudan (MW)**



Sources: Korkovelos et al.,[11] *WSHPDR 2013*,[12] *WSHPDR 2016*,[13] *WSHPDR 2019*[14]

RENEWABLE ENERGY POLICY

South Sudan does not have a renewable energy policy framework. Despite considerable renewable energy potential, the developed renewable energy is in the form of individual rooftop solar panels. Plans have been discussed and technical evaluations have been completed for a 20 MW solar farm financed by the African Import-Export Bank. There are also plans to build hydropower plants. The SSEC is looking for investors to build a 120 MW hydropower plant near the capital city of Juba and a 1,080 MW Grand Fula Dam near the border with Uganda, with construction expected to start within five years of securing funding. The hydropower projects proposed by the Government are all large-scale.[9]

BARRIERS AND ENABLERS TO SMALL HYDROPOWER DEVELOPMENT

The development of new SHP projects is hampered mainly by:

- A lack of feasibility studies on potential sites due to civil war;
- Focus on developing the national grid and exploiting the natural crude oil and gas reserves;
- Lack of attention to SHP projects in favour of larger hydropower projects;
- Lack of private investors due to the volatile economy and concerns over renewed armed conflicts;
- Lack of a renewable energy policy framework.

Enablers for SHP development in South Sudan include:

- Considerable identified SHP potential;
- The particularly low rate of access to electricity might influence the Government of South Sudan to provide solutions to isolated peoples in the form of SHP.

Tanzania

Wakati Ramadhani Mwaruka, Small Hydropower Centre Tanzania, University of Dar es Salaam

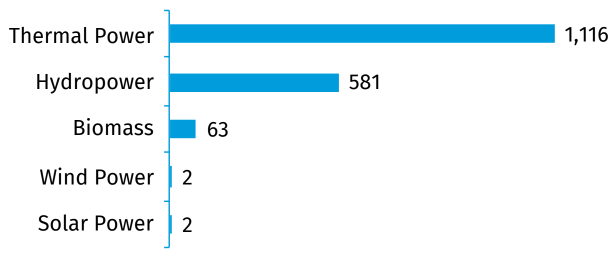
KEY FACTS

Population	57,637,628 (est. 2020)[1]
Area	948,740km^2 [1]
Topography	The landscape of mainland Tanzania is generally flat and dominated by plains along the coast, transitioning to a central plateau and highlands in the north and south. The highest peak in the country is Mount Kilimanjaro at 5,895 metres, located in the north-east.[2]
Climate	The climate in Tanzania is tropical. In coastal areas climate is hot and humid, while in the north-western highlands it is cool and temperate. There are two rainy seasons: the short rains are generally from October to December, while the long rains last from March to June. In the central plateau, climate tends to be dry and arid throughout the year.[3]
Climate Change	In 2020, annual precipitation in the country reached 1,227 mm, 198 mm above the long-term (1981–2010) average, making 2020 the fifth wettest year on record since 1970. Projections of climate change predict an increase in mean seasonal temperatures of over 2.0 °C by 2050 and of up to 3.8 °C by 2100 in various parts of the country, with increases most pronounced between June and August.[3,4]
Rain Pattern	Mean annual rainfall in Tanzania ranges from 500 mm to more than 2,500 mm. The average duration of the dry season is between five and six months. Rainfall patterns have recently become much more unpredictable, with some regions receiving extremely low or extremely high annual rainfall.[5]
Hydrology	Tanzania is surrounded by water bodies covering an area of 59,050 km^2, or approximately 6 per cent of the total area of the country. Major water bodies include the Indian Ocean on the east coast, Lake Victoria in the north-west, Lake Tanganyika in the west and Lake Nyasa in the south. River resources in Tanzania are divided into nine water basins: the Pangani River Basin, Rufiji River Basin, Lake Victoria, Wami-Ruvu, Lake Nyasa, Lake Rukwa, Lake Tanganyika, Internal Drainage and the Ruvuma and Southern River Basins. Major rivers in Tanzania include the Rufiji, Great Ruaha, Kagera, Ruvuma, Wami, Malagarasi, Mara and Pangani.[2,6]

ELECTRICITY SECTOR OVERVIEW

The total installed capacity of Tanzania as of 2022 amounted to 1,764 MW, with thermal plants (primarily gas-fired) providing 1,116 MW (63 per cent) of the total, hydropower providing 581 MW (33 per cent), biomass providing 63 MW (4 per cent) and other energy sources, including wind and solar power, providing 4 MW (less than 1 per cent) (Figure 1).[7]

Figure 1. **Installed Electricity Capacity by Source in Tanzania in 2022 (MW)**

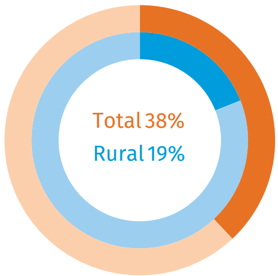


Source: USAID[7]

The country's electricity subsector is dominated by the grid network owned by the state-owned company Tanzania Electric Supply Company Limited (TANESCO). However, the 2009 Electricity Act opened the sector for private companies and ended the 40-year monopoly held by TANESCO. The penetration of independent power producers (IPPs) so far has been limited but steadily increasing.

Domestic generation of electricity in Tanzania during the 2019/2020 fiscal year reached 7,594.3 GWh, while imports amounted to 111.3 GWh. TANESCO accounted for 81 per cent of the domestically-generated electricity, while IPPs accounted for the remaining 19 per cent.[8] According to the World Bank, access to electricity in 2019 was approximately 38 per cent nationwide and 19 per cent in rural areas (Figure 2).[9] Peak electricity demand in 2018 was 1,045.7 MW and is projected to reach approximately 4,020 MW by 2025.[10,11]

Figure 2. **Electrification Rate in Tanzania in 2019 (%)**



Source: World Bank[9]

Despite the abundance of small hydropower (SHP) resources in most parts of the remote areas of Tanzania, the rural areas of the country remain virtually unelectrified. For many years the country's rural electrification efforts were focused on grid extension, which has proved to be economically unsustainable and financially prohibitive. Decentralized renewable energy has been considered as an alternative to shift the country's focus from grid extension to rural electrification. The Rural Energy Act of 2005 established the Rural Energy Board, Rural Energy Fund and Rural Energy Agency, which are responsible for the promotion of improved access to modern energy in rural areas. Standardized Power Purchase Agreements (SPPA) and Standardized Power Purchase Tariffs (SPPT) have been established specifically for small power producers. Since the country's energy sector reform in 2005, there has been a considerable increase in electrification rates in urban and rural areas, which has been largely underpinned by the efforts of the Government in deploying renewable energy technologies, including hydropower. These efforts have resulted in nearly 70 per cent of rural villages achieving electricity access by the end of 2021.[12]

In December 2020, TANESCO entered into an agreement with six renewable energy producers to purchase 19.16 MW of generation capacity to be connected to the national grid in various parts of the country. The agreement includes 10 MW from the Kahama solar power project, 5 MW from the Kigoma solar power project, 1.7 MW from the Madope hydropower project, 1.2 MW from the Maguta hydropower project, 0.9 MW from the Luponde hydropower project and 0.36 MW from the Ijangala hydropower project, developed by Nishati Lutheran Investment.[13] Furthermore, development of the privately-owned 5.39 MW Kitewaka SHP project is underway, with construction to commence in 2022.[14]

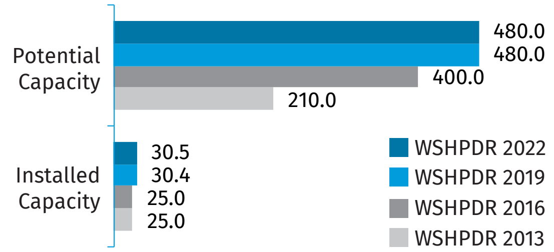
The biggest power infrastructure project in Tanzania in recent years is the 2,115 MW Nyerere hydropower plant, with construction ongoing as of 2021.[15] The project is expected to greatly boost electricity generation in the country upon completion, reducing both generation costs and end-user electricity tariffs.

Electricity tariffs for consumers in Tanzania are approved by the Energy and Water Utility Regulatory Authority (EWURA) and are divided into categories based on consumer type and electricity use. Service and energy charges were last reviewed in 2016, with the average tariff set at 250.62 TZS/kWh (0.11 USD/kWh).[16]

SMALL HYDROPOWER SECTOR OVERVIEW

Tanzania defines SHP plants as hydropower plants with an installed capacity below 10 MW. The installed SHP capacity of Tanzania is estimated at approximately 30.5 MW as of 2022, including isolated and off-grid SHP plants. The total estimated potential SHP capacity is 480 MW, indicating that approximately 6 per cent has been developed so far.[6,17,18,19] Relative to the *World Small Hydropower Development Report (WSHPDR) 2019*, installed SHP capacity increased marginally by less than 1 per cent due to a new SHP plant commissioned in 2019, while potential SHP capacity remained the same, owing to lack of up-to-date studies of SHP potential (Figure 3).[6]

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Tanzania (MW)**



Source: *WSHPDR 2019*,[6] Small Hydropower Centre Tanzania,[17] Michael,[18] Kassana et al.,[19] *WSHPDR 2013*,[20] *WSHPDR 2016*[21]

Most of the developed SHP projects in Tanzania are owned by private entities and are not connected to the national electricity grid. For many years, SHP development was promoted mainly by missionaries for provision of power to community facilities such as health centres, schools and vocational centres. Grid-connected SHP plants contribute just 15 MW of the total installed SHP capacity. Five SHP plants in the 300–8,000 kW range are owned by TANESCO, while faith-based groups operate more than 1,617 SHP plants, with a range of capacities from 15 kW to 800 kW and an aggregate capacity of 2 MW. A partial list of existing SHP plants in the country is displayed in Table 1, while several ongoing SHP projects are listed in Table 2.[17]

A number of surveys have been carried out assessing SHP potential in Tanzania. At least four different studies have identified hundreds of potential SHP sites in different parts of the country, with estimates of total potential capacity ranging between 77.76 MW and 408.12 MW. Considering a probable degree of overlap between these studies, the total potential SHP capacity in the country is somewhere in the 300–500 MW range, with 480 MW considered a reasonable upper limit.[17,18,19,22]

The most recent comprehensive assessment of the SHP potential in Tanzania was carried out by the World Bank in 2017 through its Energy Sector Management Assistance Program (ESMAP), under close supervision of the Rural Energy Agency. Several prospective SHP sites identified by ESMAP are listed in Table 3.

RENEWABLE ENERGY POLICY

While there is no comprehensive renewable energy policy in Tanzania, the Government has issued policy statements and legislation that include provisions in support of renewable energy. These include the Rural Energy Act of 2005, which established the Rural Energy Agency and Rural Energy Fund, as well as the Electricity Act of 2008, which established procedures for the diversification of generation sources. The SPPA/T framework established by EWURA provides additional regulatory support for small producers and is reviewed annually to reflect operating costs. As of 2018, a renewable energy feed-in tariff (REFIT) policy draft was under review by EWURA.[24]

Small-scale power producers (0.1–10 MW) based on RES are regulated by EWURA under the small power projects (SPP) framework, which assigns technology-specific standardized power purchase tariffs (SPPT) based on a capacity range. SPPTs effective as of May 2019 are displayed in Table 4.

Table 4. **Standardized Power Purchase Tariffs for Small Power Producers in Tanzania in 2019**

Capacity (MW)	*Price (USD/kWh)*				
	SHP	*Wind power*	*Solar power*	*Biomass*	*Bagasse*
0.10–0.50	0.1065	0.1082	0.1054	0.1015	0.0971
0.51–1.00	0.0990	0.0995	0.0984	0.0934	0.0909
1.01– 5.00	0.0895	0.0942	0.0924	0.0864	0.0856
5.01–10.00	0.0783	0.0888	0.0834	0.7600	0.0755

Source: EWURA[25]

Additionally, EWURA applies separate regulations to very small power projects (VSPPs) up to 100 kW, which are able to set retail tariffs without EWURA's approval. To qualify for the VSPP status, a project must meet several thresholds including a return on equity of 18.5 per cent, a debt-to-equity ratio of 70:30 and a depreciation period of 20 years, among others. SHP up to 100 kW must have a capacity factor of no less than 55 per cent to qualify for the VSPP status.[25,26]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

Tanzania has nine Basin Authorities, which in addition to other functions are responsible for issuing water permits to water users (including SHP developers and operators) as well as for annual fee collection from permit holders. The developer must submit project details to the relevant Basin Authority prior to the start of the project in order to receive the water use permit. After receiving the permit, the developer pays annual water use fees based on the volume of water used for power generation.

COST OF SMALL HYDROPOWER DEVELOPMENT

SHP projects in Tanzania are heavily reliant on imported technology and foreign expertise, driving up development costs. The 850 kW Ifumbo hydropower plant, constructed in 2008, carried a total project cost of USD 5.5 million, indicating a cost of USD 6,470 per installed kW. Funding for this project was largely provided by a Swiss donor.[27] The ongoing construction of the Kitewake SHP plant, with a total planned capacity of 5.39 MW, is expected to cost a total of USD 21 million, or 3,896 USD/kW. Meanwhile, two run-of-river cascades currently under construction in the Rift Valley and the Great Ruaha Basin, consisting of several plants and totalling 17 MW of planned capacity each, will cost USD 46 million and USD 65 million, with respective costs of 2,706 USD/kW and 3,824 USD/kW.[28] These numbers indicate a clear cost-saving trend as projects increase in scale.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Observed and projected changes in the hydrological regime in Tanzania both point to an increase in surface runoff and precipitation in the coming decades. Climate projections under the RCP8.5 scenario indicate an increase of as much as 27 per cent in annual precipitation by the mid-21st century. Surface runoff is expected to increase by anywhere from 13 per cent to 94 per cent during the same period across the country, with certain watersheds experiencing an increase of up to 160 per cent.[29] While gradual increases in runoff could be beneficial for the long-term sustainability of hydropower generation in the country, extreme locally concentrated runoff events and flooding could pose a threat to hydropower infrastructure in those areas.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Tanzania is endowed with abundant SHP potential but most of the surveyed sites have not yet been developed. The major challenges hampering SHP development in the country are summarized below:

- Low financial sustainability for project developers including NGOs and municipal authorities;
- Lack of local expertise and human resource development in the SHP sector, additionally hampered by a framework that tends to concentrate knowledge and talent in government ministries and cause a lack of qualified third-party personnel at the local level, particularly in rural areas;
- Lack of local technology and manufacturing capacity for SHP;
- Inability of rural customers to bear the financial burden of power infrastructure development;
- Lack of long-term planning with regard to rural electrification;
- Insufficient information about potential sites and other hydrological data, with existing inventories not exhaustive or up-to-date;
- Inadequate development incentives and awareness of the benefits of SHP;
- Lack of joint ventures in the form of public-private partnerships.

Enablers for SHP development in Tanzania include the following:

- Substantial existing untapped SHP potential across the country;
- Abundant water resources and stable prospects for water resource exploitation even in the face of climate change;
- Existing studies and surveys mapping hundreds of potential SHP sites;
- Substantial national experience with SHP development and generation;

- Government policy supportive of off-grid generation and small power plants as the primary means of rural electrification.

Uganda

George Kimbowa, Wageningen University and Busitema University

KEY FACTS

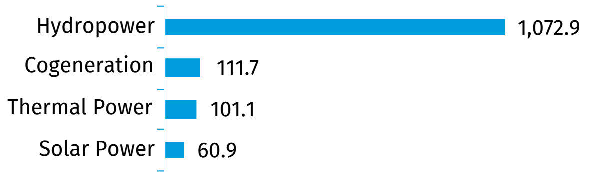
Population	44,269,594 (est. 2020)[1]
Area	241,551 km^2 [2]
Topography	The topography of Uganda mainly consists of a plateau with heights ranging from 800 metres to 2,000 metres. The country is bounded by several mountain ranges including the Rwenzori Mountains along the western border, with Margharita Peak on Mount Stanley, the third highest in Africa, rising to 5,109 metres, and Mount Elgon rising to 4,320 metres. The Western Rift Valley runs north to south through the western half of the country. The lowest point in Uganda is at 621 metres on the surface of Lake Albert.[3]
Climate	Uganda has a generally warm, tropical climate varying from a rainforest/monsoon climate in the south-east to a savannah climate in the north. The country's mean annual temperature is approximately 26 °C, with maximum temperatures between 18 °C and 31 °C and minimum temperatures between 15 °C and 23 °C. Temperatures are lower in the south-west and higher in the north and north-east, where the country experiences semi-arid conditions. Seasonally, temperatures are coolest between June and August and warmest from December to May.[4,5]
Climate Change	Climate change projections for Uganda vary according to different scenarios, but an increase by 1.5–2.0 °C is projected by the 2060s and by as much as 2.5 °C by the 2090s under RCP4.5, relative to the 2010s. Under RCP8.5, an increase of as much as 5.0 °C is projected by the 2090s.[6]
Rain Pattern	Uganda receives an annual rainfall ranging from 400 mm for the eastern Karamoja region to 2,800 mm for the Lake Victoria and Mountain Elgon regions, with an average of 1,180 mm.[6,7] The country experiences two rainy seasons, with heavy rains from March to May and lighter rains from October to December. The dry seasons are from December to February and from June to August.[4]
Hydrology	Most of Uganda belongs to the Nile drainage basin, except a small portion in the north-east of the country that drains into the Lake Turkana and Lotikipi basins in Kenya. Approximately 16 per cent of the total land area of the country is covered by wetlands and open water, with the south-east dominated by Lake Victoria, the source of the White Nile River, which extends into neighbouring Kenya and Tanzania.[7] The White Nile flows north, connecting Lake Victoria, Lake Kyoga in Central Uganda and Lake Albert on the border with the Democratic Republic of the Congo.[2] The Albert Nile flows northwards out of Lake Albert into South Sudan. Other major waterbodies in Uganda include Lake George and Lake Edward, located along with Lake Albert in the western arm of the East African Rift Valley. Most of the lakes in Uganda are transboundary, with the exception of Lake Kyoga and Lake George.[8]

ELECTRICITY SECTOR OVERVIEW

Uganda is endowed with a variety of natural energy resources, including both renewable and non-renewable energy sources such as hydropower, biomass, solar power, geothermal power, peat and fossil fuels. Biomass is the predominant energy type in Uganda, accounting for 94 per cent of the country's total energy consumption. In terms of power generation, the renewable energy power generation potential of Uganda is estimated at 5,300 MW. This includes over 2,000 MW of hydropower potential, 1,650 MW of biomass cogeneration potential and 450 MW of geothermal power potential. Uganda additionally has considerable peat reserves estimated at 250 million tons and an average daily irradiation of 5.1 kWh/m^2.[9]

The total installed capacity in Uganda was 1,346.6 MW in 2021, including hydropower with 1,072.9 MW (approximately 80 per cent of the total), bagasse-fired cogeneration plants with 111.7 MW (8 per cent), thermal power with 101.1 MW (8 per cent), and grid-connected solar power with 60.9 MW (5 per cent) (Figure 1).[10] Over the last 20 years the installed capacity of Uganda has more than tripled, amounting to just 400 MW in 2000. By mid-2022, total installed capacity in the country was expected to increase by another 600 MW with the upcoming commissioning of the Karuma hydropower plant.[11,12]

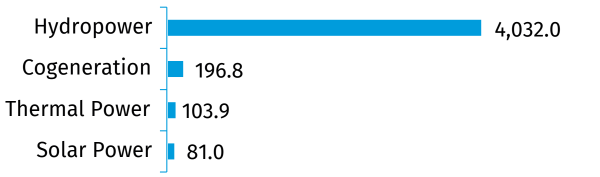
Figure 1. **Installed Electricity Capacity by Source in Uganda in 2021 (MW)**



Source: ERA[10]

In 2019, total generated electricity amounted to 4,413.7 GWh, with hydropower accounting for 4,032.0 GWh (91 per cent of the total), cogeneration for 196.8 GWh (4 per cent), thermal power for 103.9 GWh (approximately 2 per cent) and solar power for 81.0 GWh (less than 2 per cent) (Figure 2). While overall electricity generation has been rising steadily since 2015, the contribution of thermal power has been on the decline since 2017, underlining the ongoing shift towards renewable energy sources, particularly, the expansion of hydropower and solar power[13]

Figure 2. **Annual Electricity Generation by Source in Uganda in 2019 (GWh)**

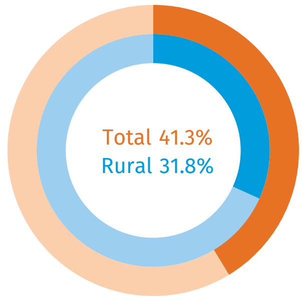


Source: ERA[13]

The single bulk supplier of electricity in Uganda, Uganda Electricity Transmission Company Limited (UETCL), purchased 4,329.4 GWh of electricity during the 2019/2020 fiscal year and sold 4,171.4 GWh, with transmission losses (approximately 4 per cent) accounting for the difference. Electricity sales are partially driven by exports to neighbouring countries including Kenya, Tanzania, Rwanda and the Democratic Republic of the Congo. During the 2019/2020 fiscal year, electricity exports amounted to 220.8 GWh, a 7 per cent decrease from the previous fiscal year.[14] The decline in exports was largely caused by declining demand in Kenya, which has been improving domestic generation and transmission capacities in the regions importing electricity from Uganda. The previous high demand in Kenya for electricity from Uganda was driven in part by an earlier price reduction of nearly 50 per cent on electricity from the latter. As such, Uganda has been gradually losing revenue from electricity exports.[15]

According to the World Bank estimates, the national rate of access to electricity in Uganda was 41 per cent in 2019, with almost 71 per cent access in urban areas and 32 per cent in rural areas (Figure 3). Access to electricity has been improving rapidly over the last few years, having stood at 19 per cent nationwide in 2015.[16] However, Uganda still has one of the lowest levels of per capita electricity consumption in the world at 215 kWh per year, compared to the Sub-Saharan Africa average of 552 kWh per capita and the world average of 2,975 kWh per capita.[17] Electricity consumption is dampened by significant electricity export volumes.

Figure 3. **Electrification Rate in Uganda in 2019 (%)**



Source: World Bank[16]

The demand for electricity has been growing at an average annual rate of 10–12 per cent. The number of customers connected to the grid has also been increasing rapidly, from a total of 801,667 in 2015/2016 to 1,620,505 in 2019/2020, driven primarily by the expansion of connectivity in the domestic sector.[17,18] Domestic peak demand had declined in 2020 from an average of 650 MW to approximately 530 MW due to the impact of the COVID-19 pandemic, but recovered later in the year and reached a maximum value of 689 MW in December.[15,19] In anticipation of growing demand, the Government has undertaken several large hydropower projects, including the aforementioned ongoing 600 MW Karuma hydropower project, as well as the 183-MW Isimba Falls hydropower plant commissioned in 2019.[20] A key element in the energy sector policy of Uganda is the Uganda Vision 2040 strategic plan, which identifies electricity generation as a key intervention for ensuring the socioeconomic transformation of the country. With Uganda having met the 2020 target of 30 per cent electricity access, the plan aims to reach 80 per cent access by 2040, targeting an increase of approximately 6 per cent year-on-year.[2]

Prior to 2001, all generation, transmission, distribution, sale, import and export of electricity in Uganda was managed by the Uganda Electricity Board (UEB), a mandated monopoly. In 2001, UEB was unbundled into three separate companies in line with the stipulations of the Electricity Act of 1999. The Uganda Electricity Generation Company Limited (UEGCL), the UETCL, and the Uganda Electricity Distribution Company Limited (UEDCL) are now each responsible for generation, transmission and distribution of electricity, respectively. In addition to UEGCL, generation is also carried out by a number of independent power producers (IPPs), including Eskom Uganda Limited and public-private partnerships (PPPs). Private companies also play a significant role in electricity distribution. These include Umeme Limited, West Nile Rural Electrification Company (WENRECo), Bundibugyo Electricity Cooperative Society (BECS), Kyegegwa Rural Energy Co-operative Society (KRECS), Pader-Abim Community Multi-Purpose Electric Co-operative Society (PACMECS), Kilembe Investments Limited (KIL), Hydromax and Kalangala Infrastructure Services Limited (KIS). The emergence of private distribution companies in recent years has been one of the factors behind the significant rise in electricity access across the country.[11,21]

The Electricity Regulatory Authority (ERA), established in 2000, is the legal supervisor of the electricity sector and is mandated by the Electricity Act of 1999 to issue licences for electricity generation, transmission, distribution, sale, import and export, in addition to establishing a tariff structure and approving rates of charges, among other functions. The UETCL negotiates prices with power generation companies through power purchase agreements (PPAs) subject to approval by the ERA. Power is sold to distribution companies at a bulk supply tariff (BST), reflective of the power purchase and transmission costs. The distribution companies then sell electricity to the end users in line with an ERA-approved tariff schedule. The setting and approval of end-user electricity tariffs considers changes in macro-economic factors such as fluctuations in international fuel prices, the variation of the currency exchange rate (UGK/USD), local and international inflation levels and energy generation mix.[1,21,22]

The largest electricity distribution agency in Uganda is Umeme Limited. Tariffs for end users purchasing electricity from Umeme Limited are updated quarterly, with tariffs for the period July–September 2021 ranging from 177.5 UGX/kWh (0.05 USD/kWh) to 816.9 UGX/kWh (0.23 USD/kWh).[23]

SMALL HYDROPOWER SECTOR OVERVIEW

The definition of small hydropower (SHP) in Uganda is hydropower plants with an installed capacity of up to 20 MW.[2] However, for the purposes of comparison with the *World Small Hydropower Development Report (WSHPDR) 2019*, the up to 10 MW definition of hydropower will also be referred to in the current chapter.

In Uganda, SHP plants are largely privately owned and operated by IPPs, with some supplying electricity to isolated grids. As of 2022, 25 SHP plants up to 20 MW were operating in Uganda with a total installed capacity of 186.0 MW. Of these, 20 plants were up to 10 MW, with a total installed capacity of 107.9 MW.[2,10,21,24] The most recent estimate of potential capacity for SHP of up to 20 MW was approximately 400 MW, while potential capacity for plants up to 10 MW is estimated at 214.1 MW, based on the combined total of existing SHP plants, ongoing projects and identified potential SHP sites.[2,21,25-27] This suggests that approximately 50 per cent of estimated SHP potential has already been developed in the country. Compared to the *WSHPDR 2019*, the installed capacity of SHP up to 10 MW in Uganda has more than doubled, due to the construction of many new SHP plants in recent years (Table 1). Meanwhile, the estimate of potential capacity for SHP up to 10 MW increased by approximately 7 per cent, due to more accurate data on existing SHP plants and planned projects (Figure 4).[27]

In recent years, intensive SHP construction has been taking place in Uganda. As of 2020, there were 20 SHP projects in various phases of completion with a total potential capacity of 141.8 MW, of which 91.8 MW were for SHP of up to 10 MW; however, by 2022 three of these projects had been completed, including the 6 MW Nyamasagani-2 SHP plant, leaving the remaining undeveloped capacity up to 10 MW at 85.8 MW. Additionally, 20 potential SHP sites of up to 10 MW have been identified with a total estimated potential capacity of approximately 20.4 MW.[10,21,24-27] Several ongoing SHP projects and identified potential SHP sites are listed in Tables 2 and 3, respectively.

The cost of SHP development in Uganda is considerable, averaging approximately USD 3–4 million per installed MW.[2] Nevertheless, SHP development is considered an important element of poverty reduction efforts in Uganda, especially for isolated rural communities suffering from poor or non-existent connectivity to the national grid.

RENEWABLE ENERGY POLICY

The Renewable Energy Policy of Uganda, adopted in 2007, aims to increase the use of modern renewable energy sources through the introduction of the feed-in tariff (FIT) remuneration mechanism and standardization of PPAs. The objective is to encourage both individual investors and companies to invest in renewable energy generation in Uganda. The policy mandated the publication of a standardized PPA with FITs determined periodically; the creation of a renewable energy department; promotion of biofuel cultivation, in collaboration with the National Forestry Authority (NFA) and Ministry of Agriculture, Animal Industry and Fisheries (MAAIF); and the development of appropriate legislation and financial incentives for the production of biofuels.[37]

Renewable Energy Feed-in Tariffs (REFITs) introduced under the Renewable Energy Policy apply to renewable energy power plants of installed capacity of 0.5–20 MW, including

SHP plants. However, to qualify for REFIT, renewable energy projects must be connected to the national grid and must represent the development of additional capacity, whether on existing power plants or through the construction of a new power plant. Existing capacities are thus excluded from applying for support under the REFIT programme. The REFIT should be able to translate into cash revenue that will not require the investor to resort to a capital subsidy and be included in the standardized PPA. Initially, REFITs were structured to differentiate between peak, shoulder and off-peak prices, to reflect the higher value of power in the peak period, as well as between short-to-medium and long-term prices to reflect the higher risk of load shedding in the short to medium term. Subsequently, REFITs were simplified to a single rate based on installed capacity only.[2,37,38]

For the period 2021-2023, base REFIT tariffs for hydropower of 0.5–20 MW were set as follows, with a 20-year guaranteed payment period:

- 0.5–5 MW: 0.0792 USD/kWh;
- 5–10 MW: linear tariff structure ranging from 0.0751-0.0792 USD/kWh, with each 0.1 MW increment assigned a progressively lower tariff;
- 10–20 MW: 0.0751 USD/kWh.[38]

Further financial support for renewable energy projects became available with the adoption of the Global Energy Transfer Feed-in-Tariff (GET-FIT) in 2013. The GET-FIT is applied on top of the REFIT as a result-based subsidy on a per kWh basis, to cover the difference between the REFIT and the Levelized Cost of Electricity (LCOE). GET-FIT is assigned in the form of grants through a competitive bidding process.[2,39] The significant recent improvements in the distribution and access to electricity in Uganda are in large part owed to the favourable regulatory environment created by the Renewable Energy Policy.

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

Developers of renewable energy sources apply for a generation licence or licence exemption with the ERA and applications are processed within a maximum of 180 days following submission. Additional licensing bodies include the Directorate of Water Resources Management (DWRM) for the water abstraction permit; the National Environment Management Authority (NEMA) for the environmental permit; and UETCL, which concludes the PPA agreement with the power producer. The licensing process for SHP also involves the publication of notices in the National Gazette and the national newspaper to solicit any potential objections to the project from other potential stakeholders. The Hydro Power Association of Uganda (HPAU), a non-profit organization that brings together private hydropower development companies in Uganda, is involved in the promotion of and lobbying efforts for SHP.[40,41]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Climate change projections for Uganda under RCP4.5 predict little change in annual precipitation, with fluctuation within the range of ±10 per cent by 2065–2095, relative to 2015. Seasonally, large increases in winter rainfall of upwards of 100 per cent are possible, while regionally, a decrease of up to 20 per cent is likely in the Lake Victoria area. Under RCP8.5, significant decreases of up to 30 mm per month are possible in the southern part of the country by 2065–2095.[6] As Uganda is heavily dependent on hydropower, fluctuations and changes in regional precipitation distribution could have potentially far-reaching effects. In 2003–2007, a particularly severe drought decreased hydropower generation in the country by over 60 per cent.[2] According to some calculations, available hydropower capacity may decline by as much as 26 per cent by 2050 relative to 2025, although other models predict an increase of approximately 15 per cent over the same period. The uncertainty of projections suggests that the impact of climate change on hydropower will be manageable as long as the Government maintains course with its current large-scale expansion plan in the sector.[6]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Although the development of SHP in Uganda has accelerated in recent years, it still faces a number of significant obstacles, including the following:

- Access to electricity primarily hampered by poor transmission and distribution infrastructure despite growth of generation capacity;
- Potential for adverse environmental impacts due to institutional and legal weaknesses, in particular poorly implemented environmental and social impact assessments (ESIA);
- Bureaucratic, complex and slow land acquisition process that affects overall project costs and timely construction of transmission line infrastructure;
- Limited local manufacturing capability for hydropower equipment as well as insufficient implementation experience and technical capacity;
- The need for substantial upfront investment capital;
- Social concerns including the resettlement and compensations for populations affected by development projects.

Factors enabling SHP development in Uganda include:

- The 'unbundling' of the state-owned Uganda Electricity Board (UEB);
- The establishment of a Rural Electrification Agency (REA) by the Government of Uganda to promote on-grid and off-grid rural electrification led by the private sector;
- Government investment in least-cost power technologies to provide adequate and reliable service;

- Collaboration with the East African Community on regional power interconnection;
- Conducive regulatory environment and incentives aimed at diversifying the country's generation mix.

Zambia

Ernest Banda, Kangwa Bwembya, Reynolds Mukuka and Oscar Sinkala, ZESCO Ltd.

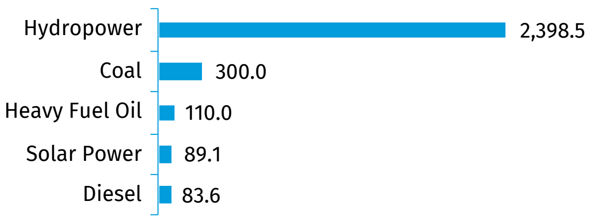
KEY FACTS

Population	17,885,422 (2020)[1]
Area	752,612 km^2[2]
Topography	The country is located on the great plateau of Central Africa, at an average altitude of 1,200 metres and rises to a higher plateau in the east. The country has three main topographical features: mountains, with an altitude of at least 1,500 metres; a plateau, with an altitude ranging from 900 metres to 1,500 metres; and lowlands, with an altitude of 400–900 metres.[3]
Climate	There are three seasons in Zambia: cool and dry from May to August, hot and dry from September to November and warm and wet from December to April. In the warm wet season, frequent heavy showers and thunderstorms occur. Average temperatures are moderated by the height of the plateau. In the cool season maximum temperatures vary from 15 °C to 27 °C, with morning and evening temperatures as low as 6–10 °C and occasional frost on calm nights in valleys and hollows which are sheltered from the wind. During the hot season maximum temperatures range from 27 °C to 35 °C.[4]
Climate Change	Zambia has continued to experience climate change and climate variability. The projected climate change impacts include: rises in temperature, shifts in precipitation and possible increases in the frequency and intensity of weather events. The country has experienced some of its worst droughts and floods in the last two decades. The mean annual temperature in Zambia has increased by 1.3 °C since 1960, representing an average increment rate of 0.29 °C per decade. Meanwhile, the mean annual rainfall over the country has decreased by an average rate of 1.9 mm per month (2.3 per cent) per decade since 1960. The mean annual temperature is projected to increase by 1.2–3.4 °C by the 2060s and by 1.6–5.5 °C by the 2090s. The proportion of total rainfall coming from extreme precipitation events, sometimes resulting in flooding, is expected to increase. The future trends in the country are towards higher average temperature, erratic precipitation and possible decrease in total rainfall.[3]
Rain Pattern	Zambia receives moderate rainfall ranging from an annual average of approximately 600 mm in the south of the country to over 1,400 mm per year in the north. The country's annual average rainfall is 1,000 mm. The rainfall pattern over the whole country is similar, with most precipitation falling between November and March, but the amount of rain varies considerably. In the north of the country rainfall is 1,250 mm or more a year, decreasing southwards to Lusaka where it is approximately 750 mm annually. South of Lusaka rainfall is dictated more by the east and south-east trade winds. Rainfall in this area is 500–750 mm.[5]
Hydrology	The country has five main rivers: Zambezi, Kafue, Luangwa, Luapula and Chambeshi. The five main river basins incorporate the several small river basins at which small hydropower potential is vast. The country's major lakes are Tanganyika, Mweru, Mweru Wa Ntipa, Bangweulu and the artificial lakes include Kariba and Itezhi-tezhi. Large hydropower plants are mainly located in the lower areas of the above catchments, while the small hydropower potential is mainly concentrated in the upper areas.[3,6]

ELECTRICITY SECTOR OVERVIEW

The electricity generation mix in Zambia is predominantly made up by hydropower. In the fourth quarter of 2019, of the total installed capacity of 2,981 MW hydropower accounted for 80 per cent (Figure 1). The remainder of the generation mix was composed of coal (300 MW, 10 per cent), heavy fuel oil (110 MW, 4 per cent), solar power (89 MW, 3 per cent) and diesel (84 MW, 3 per cent).[7]

Figure 1. **Installed Electricity Capacity by Source in Zambia in 2019 (MW)**

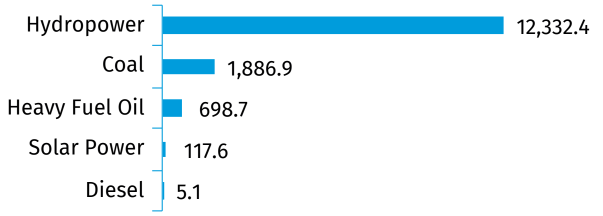


Source: ERB[9]

In 2019, the country's installed capacity increased to 2,981.2 MW from 2,898.2 MW in 2018, representing a near 3 per cent increase. This was mainly attributed to the commissioning of the 54.3 MW Bangweulu and 34 MW Ngonye solar power plants as well as the 67 kW of solar-powered micro-grids. On the other hand, the Zambia Electricity Supply Corporation (ZESCO) decommissioned 5.28 MW of diesel power plants, including: Kabompo (2.0 MW), Zambezi (1.4 MW), Mufumbwe (0.8 MW), Lukulu (0.3 MW) and Chavuma (0.8 MW). The diesel decommissioning was largely motivated by the connecting of the districts to the national grid.[9]

Despite the increase in installed capacity, the generation sent out to the grid declined from 16,189 GWh in 2018 to 15,040 GWh in 2019, reflecting a 7 per cent decrease. This was due to a poor rainfall pattern recorded in the 2018/2019 rainy season. Of the total generation in 2019, hydropower accounted for 82 per cent (Figure 2).[9]

Figure 2. **Annual Electricity Generation by Source in Zambia in 2019 (GWh)**



Source: ERB[9]

The electricity industry in Zambia is governed by the Electricity Act of 1995 and the Electricity Amendment Act of 2003. The electricity industry was liberalized in 1995 to attract investment in power generation, transmission and distribution. Currently, it consists of the vertically integrated public utility company ZESCO Limited, independent power producers (IPPs) and power distribution companies. These entities are responsible for the generation, transmission, distribution and supply of electricity. Private sector players that provide services include Copperbelt Energy Corporation (CEC), Lunsemfwa Hydro Power Company, Maamba Collieries Ltd and Zengamina.

ZESCO owns the four main hydropower plants located in the southern part of the country: 990 MW Kafue Gorge, 720 MW Kariba North Bank, 108 MW Victoria Falls and the newly commissioned 120 MW ITT. A fifth large hydropower plant is owned by Itezhi Tezhi Power Corporation (120 MW). The country also has operational small hydropower (SHP) plants with a combined installed capacity of 89.8 MW and owned by ZESCO and IPPs.[9]

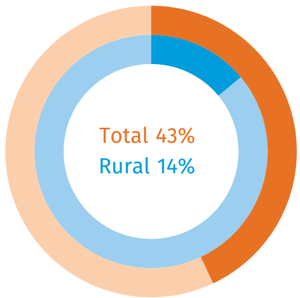
The electricity sector is overseen by the Ministry of Energy (MoE), which provides policy guidance, while the Office for Promoting Private Power Investment (OPPPI) has the role of promoting private investment in power projects. The sector is regulated by the Energy Regulation Board (ERB), which is responsible for licensing, tariff setting and monitoring the quality of supply and service standards. The Rural Electrification Authority (REA) is a statutory body that was created through the enactment of the Rural Electrification Act 2003 to increase access to electricity in rural areas.[9]

The general outlook for the electricity industry in Zambia is positive both in the short and long term. To address the current power deficit, ZESCO established a special purpose vehicle (SPV), Kafue Gorge Lower Power Development Corporation (KGLPC), to spearhead the construction of the 750 MW Kafue Gorge Lower hydropower plant at an estimated cost of USD 2.2 billion. The first unit of the plant was commissioned in July 2021.[8]

Zambia is divided into 10 provinces: Central, Copperbelt, Western, Eastern, Luapula, Lusaka, Muchinga, Northern, North-Western and Southern. Copperbelt and Lusaka are the only provinces with access to electricity above 50 per cent, while many other provinces have 10 per cent or less.[9]

In 1994, the Government established the Rural Electrification Fund (REF) by committing the sales tax to electricity and has been trying to increase the electrification rate in rural areas by executing projects funded by REF. At that time, the household electrification rate was approximately 20 per cent countrywide, and only 2–3 per cent in rural areas. As of 2019, 43 per cent of the population had access to electricity, and 14 per cent of rural population had access (Figure 3).[11]

Figure 3. **Electrification Rate in Zambia in 2019 (%)**



Source: World Bank[11]

The Government has been strengthening policies and institutions related to rural electrification. In December 2003, the Rural Electrification Act was ratified to establish the REA and to improve the management of the REF.[10] The Government, through the Rural Electrification Master Plan (REM), has set a target to increase electrification rates to 66 per cent of households by 2030, of which 90 per cent would be for urban areas and 51 per cent for rural areas.[12]

Despite the country's vast renewable and non-renewable energy sources, few of these have been developed to improve the attractiveness of the energy sector and to transfer the benefits for industrial expansion, employment creation and poverty reduction.[11,12] The development of large hydropower plants in Zambia has historically been driven by the industrial needs of energy for mining, whereas SHP development has historically been initiated to provide power to areas that are far from the national grid, areas that were extending from the Southern Province towards the Copperbelt.

ZESCO transmits power at various voltage levels, namely 330 kV, 220 kV, 132 kV, 88 kV and 66 kV.[13] These voltage levels are stepped down to 33 kV and 11 kV for distribution at substations. The main 330 kV transmission lines are running north to south in the middle of the country because the copper mines, which are the largest load centres, are located in the north and the main generation plants are located in the south. Copperbelt Energy Corporation (CEC) has most of the mining and large industrial customers, who are supplied at 66 kV or higher voltage in Copperbelt Province, while small customers within the CEC service area are supplied by ZESCO. In 2019, ZESCO recorded annual average transmission and distribution losses of 5 per cent and 11 per cent, respectively.[9] In off-grid locations, small IPPs and non-governmental organizations (NGOs) are supplying electricity with either SHP or diesel power plants through the isolated distribution network.

The country has made progress in gravitating towards cost-reflective electricity tariffs through an upward adjustment of tariffs by 75 per cent implemented in 2017, following the electricity crises of 2015 and 2016. This is after Zambia was identified as having the lowest electricity tariffs in sub-Saharan Africa in 2014.[13] In 2019, the ERB commissioned a cost-of-service study to establish the efficient cost of supplying power to various customer categories and determine the cost-reflective tariff levels. [7,14] The 2020 tariff rates for residential customers, commercial customers and social services are reflected in Table 1. Fixed monthly charges were abolished in 2020.[15]

Table 1. **Electricity Tariffs in Zambia in 2020**

Customer category	*Consumption band (kWh/month)*	*Final electricity price (ZMW (USD) per kWh)*
Residential	R1 < 100	0.47 (0.026)
	R2 101 – 300	0.85 (0.047)
	R3 > 300	1.94 (0.110)
Commercial	C1 < 200	1.07 (0.059)
	C2 > 200	1.85 (0.100)
Social Services	Schools, hospitals, orphanages, churches, water pumping & street lighting	1.19 (0.066)

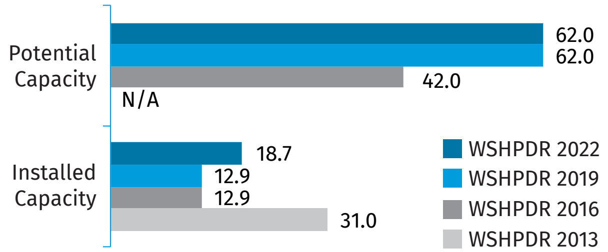
SMALL HYDROPOWER SECTOR OVERVIEW

Zambia classifies SHP plants as units between 0.5 MW and 20 MW. Plants less than 0.5 MW are regarded as micro-hydropower plants. Plants from 20 MW to 100 MW are classified as medium hydropower plants and those having installed capacities greater than 100 MW as large hydropower plants. Despite the national definition, this chapter takes the 10 MW definition, keeping consistent with previous editions of the *World Small Hydropower Development Report* (*WSHPDR)* for reasons of accurate comparison.

Based on the up to 10 MW definition, there are 18.7 MW of SHP capacity. The increase in installed capacity compared to the *WSHPDR 2019* is mainly attributed to the commissioning of the 10 MW Musonda and 0.64 MW Kasanjiku SHP plants in 2020. There has been no change in potential capacity estimates (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Zambia (MW)**



Source: ERB,[7,14,16] JICA,[10] Ministry of Energy and Water Development,[11] ZESCO LTD,[12] *WSHPDR 2013*,[17] *WSHPDR 2016*,[18] *WSHPDR 2019*[19]

Note: Data for SHP up to 10 MW.

The SHP sector in Zambia is currently undergoing a rehabilitation transformation, with the scaling-up of old plants and development of new plants being in various stages of project development. As of 2021, based on the local definition of SHP up to 20 MW, the total installed capacity for micro- and small hydropower plants stood at 60.5 MW (Table 2).[9] ZESCO Ltd is currently rehabilitating two SHP plants: the Chishimba plant is being rehabilitated and upgraded from 6 MW to 15 MW and the old Lusiwasi 12 MW plant is being replaced by new plants upstream and downstream with capacities of 15 MW and 86 MW. The Musonda plant was upgraded from 6 MW to 10 MW in 2020. In 2019, REA commissioned the 0.64 MW Kasanjiku plant in Mwinilunga district.[20]

Table 2. **List of Installed Small Hydropower Plants in Zambia**

Name	*Location*	*Capacity (MW)*	*Head (m)*	*Plant type*	*Operator*	*Launch year*
Musonda	Mansa	10.000	29	Run-of-river	ZESCO	2020

Source: ERB,[7,16] JICA,[10] Ministry of Energy and Water Development,[11] ZESCO LTD[14]

With electricity demand in Zambia projected to increase at a rate of approximately 4 per cent per annum and given the current national and regional power deficit, there is need to deal with various bottlenecks in the hydropower development process in Zambia.[21] ZESCO hydropower database, updated in 2016, indicates that the statistics of theoretical hydropower potential was on the order of 8,000 MW.[14] However, only 30 per cent of this potential has been developed to date.[11] Several SHP plants are in planning at various stages of development (Table 3).

Table 3. **List of Selected Planned Small Hydropower Projects in Zambia**

Name	*Location*	*Capacity (MW)*	*Head (m)*	*Plant type*	*Developer*	*Stage of development*
Mumbururuma	Mporokoso	18.8	33.1	Run-of-river	ZESCO	Pre-feasibility

RENEWABLE ENERGY POLICY

The policy framework governing renewable energy in Zambia is driven by the National Energy Policy. It was formulated in 1994 and sought to promote optimal supply and utilization of energy for socioeconomic development in a safe and healthy environment. Due to the realization of the strategic nature and integrated nature of energy in economic development, the National Energy Policy 1994 has been revised to ensure that the role of energy in relation to other economic dynamics are taken care of. In particular, emerging cross-cutting aspects related to sustainable industrial development were not addressed in the National Energy Policy 1994.[26] The National Energy Policy of 2019 recognizes the critical role played by renewable energy in poverty alleviation and national development. The policy also considers the need for climate change mitigation and adaptation measures while advancing the sustainable development of the sector.[14]

The demand for renewable energy has seen significant growth in recent years as the market has been exploring alternative sources of energy, with renewable energy proving to be a viable alternative. In 2016, the ERB completed developing The Renewable Energy Regulatory Framework (RERF). The RERF was developed in line with the National Energy Policy (2008), the Biofuels Regulatory Framework, the Regulatory Framework for Off-Grid Systems, the Renewable Energy Feed-in-Tariff (REFIT) Strategy and other relevant legislation. These documents individually strive to facilitate the implementation and diversification of the energy sector to promote renewable energy technologies and improve access to modern forms of energy. The RERF puts all these requirements in one document covering renewable energy-based electricity generation with the aim of achieving the following:

- Facilitating implementation of the Government's policy to diversify the energy mix and provide modern forms of energy to rural communities;

- Consolidating and rationalizing existing regulatory frameworks;
- Promoting investment by having a clear regulatory framework that outlines entry requirements for the sector;
- Providing clear internal guidelines to facilitate renewable energy deployment.[14]

In 2016, the Government of the Republic of Zambia and Kreditanstalt für Wiederaufbau (KfW) initiated the Global Energy Transfer Feed-in Tariff (GETFIT) programme. The programme is designed to leverage private sector investment into renewable energy generation projects. It intends to fast-track a portfolio of small-scale renewable energy generation projects, up to a maximum of 20 MW each, including SHP projects promoted by private developers. It is envisaged that the full implementation of the GETFIT programme will be done as soon as the REFIT Strategy is launched and is also contingent on the finalization of the following support mechanisms:

- Development of the procurement guidelines;
- Development of the Standard Implementation Agreement;
- Agreeing on the quantum of the GETFIT subsidy on the REFITs.[8]

To develop a balanced REFIT, various methodologies and options were considered. Zambia shall apply a methodology following the cost-based approach, which implements a rate of return methodology and payment calculated using costs and return expectations of project investors.[27] In 2020 39 SHP sites were approved for feasibility study rights under the program.[15]

Licences to generate electricity from renewable energy sources are to be issued by the ERB. The generation licence essentially grants the producer the right to develop, finance, construct and operate the power plant, as well as the right to sell the electricity to the off-taker. ZESCO shall be the designated buyer of all the power delivered under the REFIT programme. The details of the off-take arrangement shall be set out in a standardized, technology-neutral power purchase agreement (PPA). The term of the PPA shall be at least 20 years from the commercial operation date.[26]

The greenhouse gas (GHG) emissions of Zambia are relatively low given the country's reliance mostly on hydropower for electricity generation. However, recently, more conventional energy sources have been commissioned such as the Maamba coal-fired power plant, which started operation in 2016. As a result, CO_2 emissions per capita have been slowly increasing since 2007. Furthermore, approximately 70 per cent of energy consumed in Zambia comes from firewood and charcoal, which is both unsustainable and unhealthy for consumers. Under the framework of the Intended Nationally Determined Contributions (INDC) to the 2015 Climate Change Agreement, Zambia intends to reduce its CO_2eq emissions by 25 per cent by 2030 compared to the baseline business-as-usual scenario through domestic efforts with limited international support, and by 47 per cent with substantial international support. This is equal to a total emissions reduction of 38 MtCO_2eq, which will require an investment of USD 50 billion by 2030. This will be achieved by implementing three programmes driven by the country's Climate Response Strategy and supported by the National Policy on Climate Change and national development policies, including energy, forestry, agriculture, water, town and country planning, sanitation and transport.[28]

Zambia does not have a national uniform tariff and developers may charge different tariffs subject to regulatory approval. However, retail tariffs must be approved by the ERB, which uses the revenue requirement or rate of return methodology. In principle, cost-reflective tariffs may be proposed by developers. The country does not yet have an electricity pricing regime for behind-the-meter storage applications. Apart from the tariff, ERB also approves customer connection charges. The ERB draws its mandate to determine electricity tariffs from the Electricity Act, Cap 433, Section 8.[29]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

The relevant policies and regulations in Zambia that govern developments such as SHP projects include the following:

- Zambia National Energy Policy (2019);
- Electricity Act No. 14 of 1995;
- Energy Regulation Act Cap 436 (2003);
- Rural Electrification Act (2003);
- Zambian Grid Code 2006;
- REFIT Strategy (2017);
- Water Resources Management Act (2011);
- Environmental Management Act (2011);
- Lands Act (2015);
- National Heritage Conservation Commission Act (1989).

The feasibility study rights for the development of SHP plants in Zambia are granted by the MoE through the following process:

- Application for the issuance of feasibility study rights to the Permanent Secretary;
- OPPPI/DOE assessment of the application;
- Interim rapid grid assessment and OPPPI/DOE recommendation;
- Permanent Secretary issues a letter granting feasibility study rights.

Permitting and licensing of SHP plants involves the acquisition of land that in most cases sits under customary tenure in Zambia. Hydropower projects also require water rights and stringent health safety and environmental standards are compulsory to prevent accidents during construction or operation of power plants. All projects must comply with requirements from the regulatory government agencies. The steps for obtaining a licence for combined generation, distribution and supply of electricity for solar and hydropower plants are as follows:

- Business registration with the Patents and Companies

Registration Agency (PACRA);
- Securing land tenure rights;
- Clearance from the Department of National Parks and Wildlife;
- Concession from the National Heritage Conservation Commission (NHCC);
- Environmental permit from the Zambia Environmental Management Authority (ZEMA);
- Water use permit for power generation from the Water Resource Management Authority (WARMA);
- Investment endorsement from the ERB;
- Tariff approval from the ERB;
- Issuance of a combined licence for generation, transmission, distribution and supply of electricity.

COST OF SMALL HYDROPOWER DEVELOPMENT

The capital cost of SHP development in Zambia depends on the size of the project and existing site conditions, such as topography, geology and hydrology. Based on the estimates of planned and recently commissioned plants, capital cost ranges from USD 8.7 million for a less than 1 MW plant to USD 76 million for an 18.8 MW plant. Costs per MW of installed capacity range from USD 2.4 million to USD 14.5 million.[10,16,21,22,23,24,25]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

GETFIT Zambia has received significant contributions from the Government of Germany, which will ensure the successful implementation of the first phases of the programme. The largest share of the funds (approximately 70 per cent) will be used for subsidies for SHP projects. In the GETFIT Zambia context, such subsidies are referred to as Viability Gap Funding, designed to close the gap between the offered power tariffs and the tariff necessary for investors to achieve the required rate of return on investment. This way, substantial amounts of private capital can be leveraged to the Zambian power sector.[30]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Hydropower is directly affected by climate change in the sense that the latter alters the amount of water available for generation and potentially the seasonal distribution of runoff. Climate change has an impact on firm energy yield, the cost of energy production and plant operations. Furthermore, climate change will also affect design risks for new hydropower projects in terms of changes that will result in greater uncertainty concerning extreme weather phenomena such as flooding and droughts, which will in turn affect the project costs. Based on the report on the climate impacts on hydropower in Africa, the regional mean hydropower capacity factor is projected to decrease due to climate change by approximately 3 per cent by the year 2099 compared to the baseline period of 2010–2019.[31]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Notwithstanding the barriers and challenges highlighted, SHP development is expected to accelerate in response to recent initiatives, including studies highlighting the magnitude of the untapped SHP potential in Zambia, the transparent permitting processes, new financial incentives and the introduction of better policies. In many cases, SHP development can be achieved with minimal impact, thus supporting the country's economic and environmental goals. Further, it is anticipated that SHP will form part of the solution to the growing demand for a rural electrification programme in the country.

The Zambian hydropower industry presents great opportunities for investment and growth. However, the industry also faces challenges that include, among others, the following:
- Water resources development and management: Lack of the hydrological data necessary to adequately asses the available potential on the small river basins;
- Energy policy: Lack of a comprehensive energy policy to deal with the requirements of private plants interfacing with the national grid, for example, the feed-in-tariff has affected the process of private sector participation in hydropower generation especially SHP, which are vital for the sustainable development of rural districts;
- Transmission of power: The challenge of the cost of transporting electricity generated from renewable sources through the transmission system to the consumption centres of the country affects the bankability of projects considering that suitable hydropower potential is mainly located in remote areas of Zambia;
- Tariff structure and return on investment: The tariff structure in Zambia is still not cost-reflective;
- Financing: Access to capital markets remains a challenge for the general local private sector investors newly entering the hydropower industry. Due to the high capital investments required in hydropower, the development of SHP plants has not progressed at the pace required to meet various load requirements;
- Inability to attract investment: The challenges related to energy policies, feed-In-tariffs and cost-reflective tariffs directly affect the ability to attract investment;
- Access to sites: The poor road networks in rural areas make it difficult and expensive to carry out any work.

Despite of the barriers stated above, the hydropower industry presents great opportunities for investment and growth. In addition, the Government of Zambia has put in place enabling polices and regulations meant to attract investments in energy sector. The key enablers for the development of SHP include, among others, the following:

- The power sector was declared a priority sector under the Zambia Development Agency Act No. 11 of 2006 through the issuance of SI No. 15 of 2011. This regulation declares the building of mini-hydropower plants, solar power, thermal and hydropower plants eligible for fiscal incentives;
- The GEFIT Zambia programme aims to facilitate private sector investment in small- and medium-scale renewable energy IPPs in Zambia;
- The REFIT strategy is aimed at accelerating private investments in small- and medium-sized renewable energy projects in order to increase the number of players in the electricity subsector and ultimately increase access to clean energy services;
- Transparent project allocation procedures, with projects being committed to developers by way of feasibility study rights granted by the MoE;
- Economic incentives to encourage investment, including fiscal incentives (e.g., tax incentives), non-fiscal incentives (risk cost sharing, support of land acquisition) and a capital-smart subsidy (for projects developed under the REA);
- Migration towards cost-reflective tariffs from tariffs that were highly subsidized was commenced in 2017;
- Sufficient and sustained market for the generated electricity, with the demand for power growing at a rate of approximately 4 per cent per annum.

Zimbabwe

Shorai Kavu, Ministry of Energy and Power Development

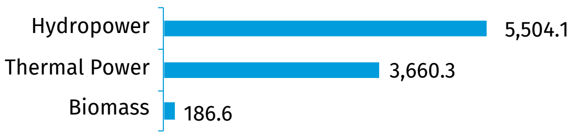
KEY FACTS

Population	14,645,000 (2019)[1]
Area	390,760 km^2 [2]
Topography	Zimbabwe is a landlocked country lying entirely within the tropics. It straddles an extensive high inland plateau that drops northwards to the Zambezi Valley, where it borders Zambia, and drops southwards to the Limpopo Valley and the border with South Africa. Zimbabwe has an average elevation of 1,500 metres above sea level and the highest peak is in the Nyangani Mountains to the north-east of the country at 2,592 metres.[3,4]
Climate	The hot season occurs from mid-August to mid-November, with daytime temperatures ranging from 26 °C to 36 °C. The rainy season is from mid-November to mid-March and can be interrupted by 4-5 dry spells. The cool season occurs from mid-May to mid-August with mild daytime temperatures ranging from 20 °C to 29 °C. The dry season occurs from mid-March to mid-May, with mild and sunny weather and temperatures ranging from 23 °C to 31 °C.[4]
Climate Change	Zimbabwe, like many other areas of Southern Africa, has increasingly been exposed to rising temperatures and increased rainfall variability due to a changing climate.[4]
Rain Pattern	The maximum rainfall is received in the eastern highlands, with annual rainfall of more than 1,000 mm. The Highveld receives an annual average of more than 500 mm of rainfall. The climate and rainfall patterns of Southern Africa have varied greatly for at least the last three centuries, leading to recurrent droughts of varying severity.[3,4]
Hydrology	Zimbabwe has six drainage basins. The largest being the Zambezi and the Limpopo basins. The western parts of the Matabeleland region are connected to the Okavango inland drainage basin through the Nata River. Parts of the Mashonaland and Masvingo regions drain through the Save River into the Indian Ocean. Two other drainage basins covering parts of the Manicaland region and draining into the Indian Ocean through Mozambique are the Pungwe River to the north and the Buzi River to the south.[3,5]

ELECTRICITY SECTOR OVERVIEW

The electricity sources in Zimbabwe include coal for thermal generation, large hydropower, small hydropower (SHP), solar power and diesel/petrol for backup systems.[6] In 2018, a total of 9,351 GWh of electricity was generated in the country, including by individual power producers (IPPs) (Figure 1). Generation from power plants owned by Zimbabwe Power Company (ZPC) increased by 25 per cent from 7,216 GWh in 2017 to 9,037 GWh in 2018, mainly due to the increased water allocation at the Kariba Dam.[7] Renewable energy generation made up 61 per cent of all electricity generation in 2018 (5,688 GWh).[7] This is a significant increase from 2017, when renewable generation made up 50 per cent. The individual contributions from the power plants in 2018 are depicted in Table 1.

Figure 1. **Annual Electricity Generation by Source in Zimbabwe in 2018 (GWh)**



Source: ZERA[7]

Note: Data for solar power generation from IPPs and off-grid sources is not publicly available and thus not included.

Table 1. **Annual Electricity Generation from ZPC and IPPs**

Power plant	*Energy source*	*Generation 2017 (GWh)*	*Generation 2018 (GWh)*
ZPC-owned plants			
Hwange	Coal	3,202.0	3,425.0
Kariba	Hydropower	3,850.0	5,377.0
Harare	Coal	75.0	66.0

Power plant	*Energy source*	*Generation 2017 (GWh)*	*Generation 2018 (GWh)*
Munyati	Coal	38.0	81.0
Bulawayo	Coal	51.0	88.0

As of 2021, Zimbabwe had a total installed capacity of 2,431 MW, of which 1,050 MW was from the Kariba South hydropower plant, 920 MW from the Hwange thermal power plant, a combined 329 MW from small coal-fired thermal plants (Harare, Bulawayo and Munyati) and 132 MW were contributed by IPPs and community-owned off-grid systems (Figure 2, Table 2). The capacity from bagasse was for the private use of sugarcane and ethanol producing firms. Available capacity stood at approximately 1,924 MW.[6,8]

The Kariba South hydropower plant extension project of 300 MW was completed in 2018 raising the plant's installed capacity to 1,050 MW.[9,10] The Hwange thermal power plant extension project with a capacity of 600 MW is under construction and expected to have the first 300 MW unit in operation by 2022 despite delays due to COVID-19 restrictions.[10,11]

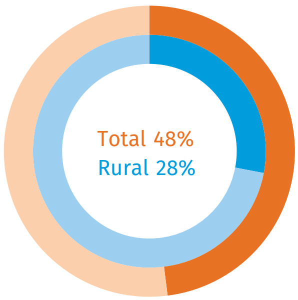
The capacity of IPPs from photovoltaic (PV) solar power plants includes the 2.5 MW Riverside power plant by Nyangani Renewable Energy Private Limited and the 2.5 MW Centragrid power plant. The Riverside power plant, commissioned in January 2018 to supply the national grid, is the first phase of the 10 MW project planned for a site in Mutoko, Mashonaland East Province of Zimbabwe.[12] The Centragrid plant is located in Nyabira, Mashonaland West Province of Zimbabwe, and was commissioned in October 2019.[13] Three planned solar power plants owned by ZPC, with 100 MW of capacity each, are yet to reach financial closure.[8]

The country imports electricity from the regional utilities to cover up for the local supply deficit: 50 MW of firm capacity from the Cahora Bassa Hydroelectric (HCB) of Mozambique and 50 MW of firm capacity from Eskom of South Africa. Variable imports operate on the Day-Ahead Market, managed by the Southern African Power Pool (SAPP) Coordination Centre. Zimbabwe has no firm capacity exports due to limited local generation capacity.[6]

According to the Zimbabwe National Statistics Agency (ZIMSTAT), the country's electrification rate was at 48 per cent in 2017 (Figure 3). Twenty-eight per cent of rural population had access to electricity and the urban electrification rate stood at 86 per cent.[14] Approximately 80–90 per cent of the rural population depend on wood fuel and kerosene for cooking and lighting according to the Zimbabwe Infrastructure Report published by the Africa Development Bank (AfDB) in 2019.[6] Food processing tasks, such as grain milling, are usually carried out with a diesel-powered system, with a few now using electricity. Although Zimbabwe is endowed with an abundance of renewable energy resources such as solar power, wind power, biomass and SHP, including run-of-river plants and inland dams, these are still not fully utilized.

Figure 3. **Electrification Rates in Zimbabwe in 2017 (%)**



Source: ZIMSTAT[14]

The energy sector in Zimbabwe is overseen by the Ministry of Energy and Power Development (MoEPD). Below MoEPD is the Zimbabwe Energy Regulatory Authority (ZERA), which ensures fairness in the sector. ZERA oversees the operations of the Zimbabwe Electricity Supply Authority (ZESA) Holdings Private Limited Subsidiaries, the oil companies and IPPs. The Zimbabwe Electricity Transmission and Distribution Company (ZETDC) and ZPC are subsidiary companies of ZESA Holdings, and the oil companies include both public and private companies. In addition, ZESA ensures fair tariffs and the quality of the provision of other services to the consumers.[7]

The national electricity grid has capacities ranging from 11 kV for low voltage to 33 kV, 36 kV, 66 kV, 360 kV and 420 kV for interconnections with the region. The grid is interconnected to the Southern African Development Community (SADC) region with the Zimbabwe grid being central. The operations of the regional grid are coordinated by the SAPP Coordination Centre, which is based in Zimbabwe.

To ensure the implementation of the country's pricing policy, Zimbabwe established the ZERA in 2012 in line with the SADC regional requirements. ZERA, in consultation with MoEPD, is responsible for the designing of the electricity pricing policy, as well as analyzing and approving tariff applications by both the state utility and the IPPs. ZERA may review tariffs for licensed operators when they apply, according to their needs. According to information recorded in the Zimbabwe Infrastructure Report of 2019 prepared by the AfDB, ZERA last reviewed the standard tariff schedule for the electricity sector in January 2013. An application for a 49 per cent tariff review was submitted by ZETDC as a bid to move from 0.099 USD/kWh to 0.147 USD/ kWh. However, after stakeholder consultations, it was resolved to keep the tariff at 0.099 USD/kWh.[6]

The tariff structure differentiates between domestic users who pay fixed charges and those who pay as per consumption levels. There is a lifeline support offered by subsidizing the first 50 kWh per month for all residents at approximately 0.02 USD/kWh. Low-demand non-residential consumers are charged both a fixed rate and flat variable rates depending on their consumption and metering system (Table 3). For comparison, the average electricity tariff in the SADC region ranges between 0.03 and 0.17 USD/kWh.[6]

Table 3. **Average Electricity Prices in Zimbabwe (USD/kWh)**

Sector	*2015*	*2016*	*2017*	*2018*
Industrial	0.0897	0.0940	0.0849	0.0804

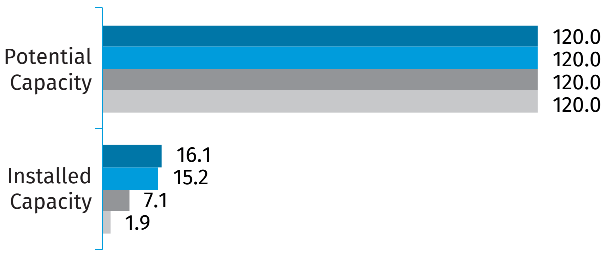
SMALL HYDROPOWER SECTOR OVERVIEW

In Zimbabwe, SHP is defined as hydropower with an installed capacity of up to 30 MW.[4,15] Based on the up to 10 MW definition, Zimbabwe had an installed SHP capacity of 16.1 MW (grid-connected and off-grid) as of December 2020.[7] The total potential capacity for SHP up to 10 MW is estimated at 120 MW according to MoEPD, which includes both reservoir and run-of-river sites.[16] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, the potential capacity remained the same, whereas the installed capacity increased by 6 per cent (Figure 4). The total installed capacity for SHP up to 30 MW in Zimbabwe is 31.35 MW, which includes a 15.25 MW power plant not included under the up to 10 MW definition of SHP.[9,16,17]

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Zimbabwe (MW)**



Source: MoEPD,[16] *WSHPDR 2019*,[17] *WSHPDR 2013*,[18] *WSHPDR 2016*[19]

Note: Data are for SHP up to 10 MW.

The off-grid systems, which are community-owned and have been sponsored by the non-governmental organizations Practical Action and Oxfarm, reached an operational capacity of approximately 400 kW by 2017.[18] The grid-connected SHP plants are privately owned by IPPs, which include Nyangani Renewable Energy (NRE), Kupinga Renewable Energy (KRE) and Bonemarrow Investments. These have separate Power Purchase Agreements (PPAs) with ZETDC as the sole owner and operator of the national grid (Table 4).[7,8]

A number of SHP projects are currently under development (Table 5).

SMALL HYDROPOWER PROJECTS AVAILABLE FOR INVESTMENT

Funding is required to update pre-feasibility and feasibility studies on several sites especially the inland dam sites. Partnerships and investors for the sites are welcome to boost electricity supply security in the country. Sites will be made available to potential investors and partners (Table 6).[8]

RENEWABLE ENERGY POLICY

Since the establishment of the Electricity Act of 2002, IPPs have been allowed to develop power generation plants.[20] There is also a National Energy Policy (NEP) that was launched in 2012, which summarizes the potential of SHP in the country and encourages the increased use of renewable energy sources in the country's energy supply mix.[21] The NEP is also supported by the country's economic blueprint, the Zimbabwe Agenda for Sustainable Socio-Economic Transformation (ZIMASSET). The ZIMASSET was succeeded by the Transitional Stabilization Programme (TSP), which was launched in 2018 and ran from October 2018 to December 2020. The focal areas of the TSP included: stabilization of the macro-economy and the financial sector; introduction of necessary policy and institutional reforms to transform to a private sector–led economy; and launch of 'quick-wins' to stimulate growth.[21] The TSP was underpinned by Vision 2030 Towards an Upper Middle-Income Country. Vision 2030 will be implemented in two phases with the first National Development Strategy launched in 2020 to run from 2021 until 2025.[22] The above documents do not elaborate much on the development of renewable energy sources, such as SHP. The country now has a National Renewable Energy Policy (REP) in place which was launched in 2019.[17] The REP promotes investment in renewable energy sources, including SHP as well as both on- and off-grid projects.[17]

Zimbabwe, through the Ministry of Environment, Water and Climate (MEWC), has prepared and submitted the Third National Communications to the United Nations Convention on

Climate Change (UNFCCC). A Climate Change Response Strategy was developed for the country, as well as a Climate Policy.[23] The country also ratified the Paris Agreement and has submitted Nationally Determined Contributions (NDCs), with hydropower development as one of the measures aimed at the mitigation of, and adaptation to, climate change effects. It is also worth noting that future hydropower development in Zimbabwe will need to ensure robustness and capability for survival against climate change effects.

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

There is no particular regulation or legislation targeting SHP development in Zimbabwe. The sector is governed by the same laws that apply to fossil fuels and other renewable energy sources. The principal law is the Electricity Act of 2002 supported by the Energy Regulatory Act of 2011. There are also the Electricity Licensing Regulations of 2008 amended by Statutory Instrument 55 of 2015. In 2018 the net-metering regulations also came into force.[21]

COST OF SMALL HYDROPOWER DEVELOPMENT

SHP projects in Zimbabwe have been developed mostly by private players and on a case-by-case basis. Therefore, the findings of feasibility studies as well as data on development costs are owned by the private developers.

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

The Infrastructure Development Bank of Zimbabwe (IDBZ) in 2019 called for a bid for consultancy to carry out feasibility studies for the Odzani power plant on the Odzani River.[24] However, there is no record of the finalization of the procurement process. ZERA developed some feed-in-tariffs (FITs), which have yet to be approved by the Government.[17] The REP has a policy statement for all SHP projects within a capacity of 30 MW to be procured through FITs once they are approved.[17]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Even though hydropower development is listed among the mitigation solutions for climate change, at the same time the sector is also at risk of being affected negatively by changes in rainfall patterns. Some negative effects have already been witnessed, as reduced water levels affected power generation at the Kariba hydropower plant during certain seasons over recent years.[25] Some climate records in the country have demonstrated that Zimbabwe is already experiencing the effects of climate change, especially rainfall variability. The induced water stress threatens to reduce the runoff necessary to sustain SHP plants, especially the run-of-river ones.[27]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Policies and regulations have a bearing on the rate of SHP development in the country. From 2011, when ZERA came into existence, followed by the NEP, the trend of SHP development has been on the rise. A greater impact is expected with the REP in place and a procurement framework being worked on by MoEPD.[8]

The following are the main barriers to SHP development in Zimbabwe:

- The effects of extreme weather conditions;
- Lack of FITs and standard procurement methods: currently tariffs are negotiated on a case-by-case basis;
- High costs of local funding: local banks offer short-term loans at high interest rates;
- Difficulties in accessing foreign funding by most potential developers: very few IPPs have managed to reach financial closure for an SHP project;
- Lack of funding for feasibility studies to ensure the bankability of projects: most project sites fail to attract funding due to the unavailability of bankable feasibility studies;
- No locally manufactured equipment: all turbines, generators and control equipment are imported.

The development of SHP in Zimbabwe is expected to be further enabled by the REP and the net-metering regulations which are now in place.[7]

1.2. Middle Africa

Countries: Angola, Cameroon, Central African Republic, Congo, Democratic Republic of the Congo, Equatorial Guinea, Gabon, Sao Tome and Principe

INTRODUCTION TO THE REGION

Middle Africa is well-supplied with water resources and hydropower is the primary source of electricity generation for most countries in the region. The exceptions include Sao Tome and Principe and Congo, which rely heavily on thermal power, and Gabon, which is well-supplied with domestic fossil fuel resources and where thermal power forms the mainstay of electricity generation along with hydropower. In other countries in the region, thermal power plays a supplementary role, providing a very significant share of installed capacity but contributing only a small share of total electricity generation. Renewable energy resources other than hydropower are represented mainly by solar power and bioenergy, although their contribution to electricity generation is minor.

In many countries in the region, nationwide electricity access stands at less than 50 per cent, with very significant disparities between urban and rural areas across the entire region apart from Sao Tome and Principe. The lack of electricity access in such countries as Angola and the Democratic Republic of the Congo, both major electricity producers, highlights the insuf-ficient connectivity and reliability of the transmission and distribution networks, with transmission and distribution losses in some countries reaching 40 per cent of total generation. In this context, distributed power generation could potentially have a positive impact on regional rates of electricity access.

An overview of the electricity sectors of the countries in the region is provided in Table 1.

Table 1. **Overview of Middle Africa**

Country	*Total population (million people)*	*Electricity access, total (%)*	*Electricity access, rural (%)*	*Total installed capacity (MW)*	*Electricity generation (GWh/year)*	*Hydropower installed capacity (MW)*	*Hydropower generation (GWh/year)*
Angola	31	46	7	5,931	17,777	3,729	12,562
Cameroon	27	65	25	1,547	7,006	950	5,230
Central African Republic	5	32	16	41	157	19	148
Congo	6	48	13	794	2,988	228	872

REGIONAL SMALL HYDROPOWER OVERVIEW

In the Middle Africa region, the definition small hydropower (SHP) as hydropower plants with an installed capacity of up to 10 MW is adhered to by Angola, the Central African Republic, the Democratic Republic of the Congo, and Sao Tome and Principe. Additionally, in Angola the up to 50 MW definition is used on occasion. In Cameroon, SHP is defined as plants up to 5 MW in the context of rural electrification programmes. No official definition of SHP exists in Congo, Equatorial Guinea and Gabon.

A comparison of installed and potential SHP capacities in the region is provided in Table 2.

Table 2. **Small Hydropower Capacities by Country in Middle Africa (MW)**

Country	*Local SHP definition*	*Installed capacity (local def.)*	*Potential capacity (local def.)*	*Installed capacity (≤10 MW)*	*Potential capacity (≤10 MW)*
Angola	Up to 10 MW	46.1	600.0	46.1	600.0
Cameroon	Up to 5 MW	1.5	N/A	1.5	970.0
Central African Republic	Up to 10 MW	18.8	41.0	18.8	41.0
Congo	N/A	N/A	N/A	0.0	70.5
Democratic Republic of the Congo	Up to 10 MW	56.0	100.9	56.0	100.9
Equatorial Guinea	N/A	N/A	N/A	7.5	31.9
Gabon	N/A	N/A	N/A	6.0	518.1
Sao Tome and Principe	Up to 10 MW	1.9	63.8	1.9	63.8
Total	-	-	-	**137.8**	**2,396.2**

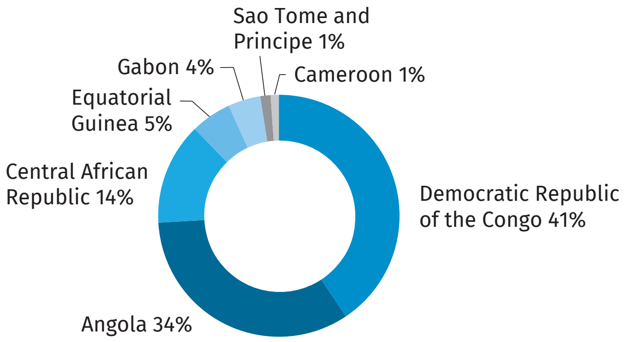
Source: *WSHPDR 2022*[1]

The total installed capacity of SHP up to 10 MW in Middle Africa is 137.8 MW, while the potential capacity is estimated at 2,396.2 MW. Relative to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed capacity has increased by 21 per cent, largely due to more accurate data becoming available on the total capacity of SHP plants in Angola. Small increases in installed capacity were also observed in Cameroon and Gabon, while in the rest of the region installed SHP capacity either remained the same or actually declined. The estimate of potential capacity increased by 29 per cent, largely due to the availability of new data on the technical SHP potential in Gabon.

SHP plays a particularly important role in the Central African Republic and Sao Tome and Principe, where it accounts for 100 per cent of installed hydropower capacity. In other countries in the Middle Africa region, the hydropower sector is dominated by large-scale plants and the contribution of SHP to the generation of electricity is relatively small. Recent activities in the SHP sector in the region have mainly focused on the rehabilitation of existing SHP plants, although one new plant was commissioned in 2021 in Cameroon.

The national share of regional installed SHP capacity by country is displayed in Figure 1, while the share of total national SHP potential utilized by the countries in the region is displayed in Figure 2.

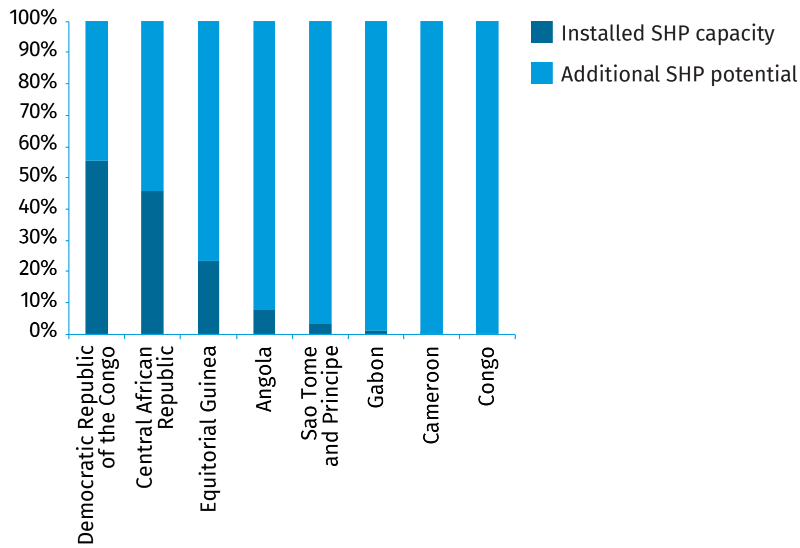
Figure 1. **Share of Regional Installed Capacity of Small Hydropower up to 10 MW by Country in Middle Africa (%)**



Source: *WSHPDR 2022*[1]

Note: Congo not included due to a lack of SHP capacity.

Figure 2. **Utilized Small Hydropower Potential up to 10 MW by Country in Middle Africa (%)**



Source: *WSHPDR 2022*[1]

The installed capacity of SHP up to 10 MW in **Angola** is 46.1 MW, while the potential capacity is estimated at 600 MW, indicating that nearly 8 per cent has been developed. The identified potential is contained in 100 different sites identified in 2015 as part of the country's Energy Strategy to 2025. Of these, at least six have been selected for priority investment by 2025.

In **Cameroon**, the installed capacity of SHP up to 10 MW is 1.5 MW, accounted for by a single SHP plant. The country's SHP potential is estimated at 970 MW, indicating that less than 1 per cent has been developed, but no detailed assessment of existing sites is available. One SHP project with an installed capacity of 2.9 MW is under development, but its commissioning was stopped due to the civil war.

The **Central African Republic** has an installed capacity of 18.8 MW for SHP of up to 10 MW, while estimated potential capacity is 41 MW, indicating that 46 per cent has been developed. The country has two SHP plants in operation, while construction of a third plant with a capacity of 10 MW was suspended due to political instability, and the plant is in need of rehabilitation.

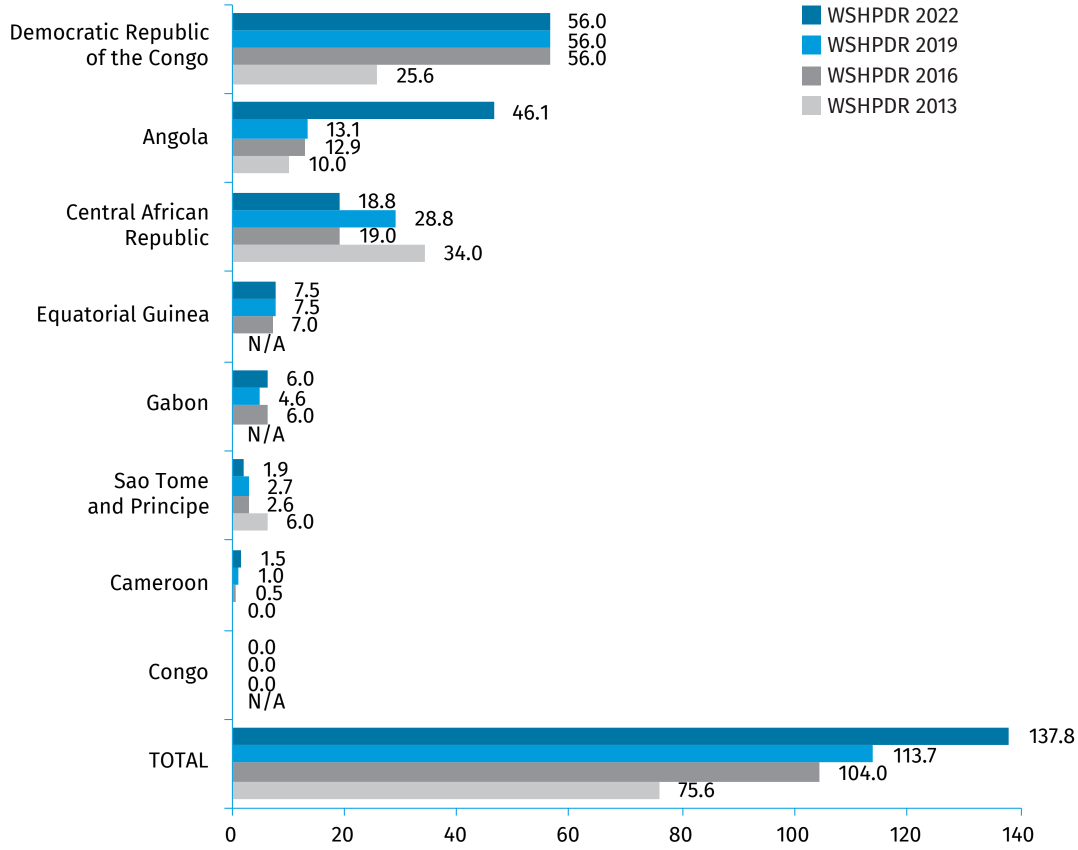
At least 15 sites suitable for SHP development have been identified in the country, and the construction of one additional SHP project is ongoing as of 2021.

There is no installed SHP capacity in **Congo**. The potential capacity for SHP has been most recently estimated at 75 MW and is entirely undeveloped. At least 27 potential SHP sites have been identified throughout the country, with capacities ranging between 6 kW and 10 MW. Several feasibility studies of potential SHP sites supported by various international institutions have been recently completed, and a number of additional studies were either ongoing or in the planning stages as of 2021.

In **the Democratic Republic of the Congo**, the installed capacity for SHP of up to 10 MW is 56 MW, while potential capacity is estimated at 100.9 MW, indicating that 55 per cent has been developed. No new SHP construction has taken place in the country in the last several years, although five new SHP projects were in the planning stages as of 2021.

The installed capacity for SHP of up to 10 MW in **Equatorial Guinea** is 7.5 MW, while potential capacity is estimated at 31.9 MW, indicating that nearly 24 per cent has been developed. There are three operational SHP plants in the country, with the largest one, the 3.8 MW Riaba SHP plant, operating at only a fraction of its installed capacity and in need of extensive repairs and upgrades. At least 36 potential SHP sites have been identified in the country and detailed evaluations of the sites are ongoing.

Figure 3. **Change in Installed Capacity of Small Hydropower up to 10 MW from *WSHPDR 2013* to *WSHPDR 2022* by Country in Middle Africa (MW)**



Source: *WSHPDR 2022*,[1] *WSHPDR 2013*,[2] *WSHPDR 2016*,[3] *WSHPDR 2019*[4]

Gabon has an installed capacity of 6 MW for SHP of up to 10 MW, provided by three SHP plants. The potential capacity is estimated at 518.1 MW, indicating that approximately 1 per cent has been developed. Recent activity in the SHP sector in the country has been limited to the refurbishment of existing plants and updated studies of the country's SHP potential.

In **Sao Tome and Principe**, the installed capacity for SHP up to 10 MW is 1.9 MW while potential is estimated at 63.8 MW, indicating that approximately 3 per cent has been developed. There is only one operational SHP plant in the country, while three others have been decommissioned and are in need of extensive refurbishment or reconstruction. Thirty-four potential SHP sites have been identified in the country, but no new SHP projects are currently planned.

Changes in the installed capacities of SHP up to 10 MW in the countries in the region compared to the previous editions of the *WSHPDR* are displayed in Figure 3.

Climate Change and Small Hydropower

Countries in the Zambezi River basin, which includes Angola, have already experienced climate change, especially rainfall variability. The projected continuous rise in evaporation and evapotranspiration due to increased temperatures could spur higher water stress in the region. However, the impacts on runoff are yet uncertain.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The main barriers to SHP development in **Angola** are the lack of stability in regulations governing asset ownership, the awarding and return of concessions, land acquisition and power purchase agreements, as well as a general lack of experience with investor relations, public-partner partnerships and Build-Operate-Transfer schemes. Additionally, the country has limited technical expertise in the SHP sector, with large hydropower taking precedence in national development.
At the same time, the large untapped SHP potential in the country and favourable topography, a multitude of identified SHP sites offer many opportunities for investment in the sector, particularly in light of increasing access to international financing.

Obstacles to SHP development in **Cameroon** include a lack of detailed assessments of SHP potential, lack of financing, unreliable infrastructure and an absence of local capacity for manufacturing electromechanical equipment. Enablers include the very significant untapped SHP potential in the country, increasing momentum in favour of renewable energy resource development and the strong need for rural electrification.

SHP development in the **Central African Republic** is hampered by a lack of incentives, monopolization of the electricity sector, which discourages investors, lack of technical capacity, limited financial resources and political unrest. However, the topography and hydrology of the country are overall favourable for SHP and projects can be undertaken with the support of a number of international institutions and financing mechanisms that have a presence in the country.

In **Congo**, barriers to SHP development include a lack of incentives and technical capacity, high cost of electricity transmission, gaps in the legal and regulatory framework regarding SHP, and expected decreases in river flow during the dry season, which could undermine the viability of run-of-river plants. The main enablers for SHP development in the country are the untapped SHP potential and a relatively liberalized electricity market.

The development of SHP in **the Democratic Republic of the Congo** is held back by the weak enforcement of the institutional and regulatory framework for private investment in the energy sector, high cost of development, lack of affordable financial mechanisms, lack of a renewable energy policy and focus on large-scale generation. The liberalization law passed in 2014 could act as an incentive for SHP development if properly enforced, allowing the country to take advantage of its substantial untapped SHP potential.

The main barrier to SHP development in **Equatorial Guinea** is the high cost of SHP relative to other energy sources, in particular subsidized fossil fuels, as well as lack of incentives for renewable energy and lack of detailed data on potential sites. The main enablers are the remaining untapped SHP potential and interest in SHP development in the country on the part of international development institutions.

Barriers to SHP development in **Gabon** include inadequate infrastructure, lack of local expertise, high costs and excessive bureaucratization. However, the regulatory environment for private investment is expected to improve and the country is aiming to transition from an oil-based economy to one reliant on renewable energy. The SHP sector is expected to benefit from the system-scale approach outlined in the Government's planned changes to the licensing process for hydropower projects, and be able to take advantage of the recently-identified and large SHP potential.

The main barrier to SHP development in **Sao Tome and Principe** is the lack of an institutional framework and policy mechanisms that would enable the realization of the country's identified SHP potential. However, SHP is seen as a promising solution for extending electricity access to the country's rural and remote areas, as well as decreasing its heavy reliance on fossil fuels.

Angola

Pedro Manso, Mathieu Barnoud & Lara Carimo, MHYD water & energy solutions sàrl

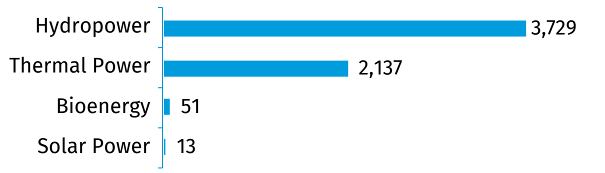
KEY FACTS

Population	31,127,674 (est. 2020)[1]
Area	1,246,700 km^2 [2]
Topography	The topography of Angola is characterized by a narrow coastal plain in the west from which rise broad tablelands lying at over 1,000 metres above sea level, a high plateau in the centre and mountain ranges to the south reaching up to 2,400 metres. The highest point is Mount Moco, at 2,620 metres above sea level, in the Huambo Province.[3,4]
Climate	The climate in Angola is tropical, with a warm rainy season from September to May and a cooler dry season from June to August. The country is divided into two climatic regions, the coast and interior. The annual average temperature ranges between a minimum of 17 °C and a maximum of 27 °C.[2]
Climate Change	Based on historical data, the mean temperature increased by 1.5 °C from 1960 to 2016. The frequency of hot days increased, while cold days decreased in the period of 1960–2003. The mean annual precipitation has been decreasing, at an average rate of 2 mm per decade. A greater decrease in late summer precipitation and increase in precipitation variability in the central-south transition area have also been observed. Climate models have predicted a continuous increase in temperature. From 2040 to 2059, an increase of 2 °C is projected, with rapid warming to take place in the interior and eastern parts of the country. There is a wide range of predictions for the change in precipitation across the country, with the predominant prediction indicating a decrease of mean annual precipitation by almost 14 mm (CMIP5 projections, RCP 8.5, Ensemble). However, the annual maximum 5-day rainfall for a 25-year period return is expected to rise by 15 mm.[5,6]
Rain Pattern	The cooler months in Angola (June–August) are very dry, with almost no rainfall. The wet season (October–April) receives between 100 mm and 250 mm of rainfall per month. The total rainfall decreases from north-east towards south and the western coast. Annual rainfall averages 984 mm.[2,4,5]
Hydrology	Most of the rivers in Angola rise in the central mountains, draining in all directions. The perennial rivers are concentrated in the north and centre, while in the south there are only three perennial rivers: the Cunene, Cuando and Cubango. Of the many rivers draining into the Atlantic Ocean, the most important ones are the Cuanza and Cunene. Other major rivers include the Cuango, draining northwards to the Congo River system, as well as the Cuando and Cubango Rivers, draining south-eastwards to the Okavango Delta in Botswana. There are no sizable natural lakes in Angola.[4,7]

ELECTRICITY SECTOR OVERVIEW

Electricity generation in Angola in 2019 was 17,777 GWh. Approximately 71 per cent of this total was from hydropower, almost 28 per cent was produced by oil- and gas-fired thermal power plants and approximately 1 per cent was from bioenergy and solar power (Figure 1).[8]

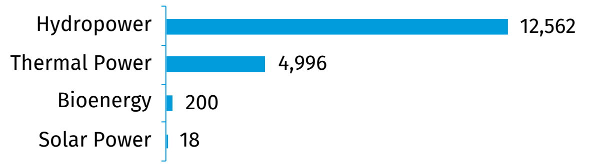
Figure 1. **Annual Electricity Generation by Source in Angola in 2019 (GWh)**



Source: IRENA[8]

In 2020, the total installed capacity of Angola reached 5,931 MW, of which 63 per cent was from hydropower, 36 per cent from thermal power and another 1 per cent from bioenergy and solar power plants (Figure 2).[8] The increase in capacity in recent years mainly originated from the hydropower plants of Cambambe 2 and Laúca, with 960 MW and 1,670 MW (five units out of six already commissioned), respectively, and the thermal combined-cycle power plant of Soyo, with 500 MW.[9]

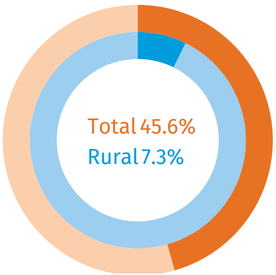
Figure 2. **Installed Electricity Capacity by Source in Angola in 2020 (MW)**



Source: IRENA[8]

In 2019, 45.6 per cent of the population of Angola had access to electricity, with almost 74 per cent access in urban areas, while the most recent data from the World Bank indicate that only 7.3 per cent of rural areas had access to electricity in 2018 (Figure 3).[10] The rate of electrification is not homogeneous throughout the country.[11] The National Company for the Distribution of Electricity (ENDE) had a total of 1,585,000 clients in 2018 divided into residential, services and industrial consumers. For comparison, in 2015 ENDE served 1,275,468 clients. Of the customers served by ENDE, approximately 200,000 were provided with electricity through prepaid meters.[9,12]

Figure 3. **Electrification Rate in Angola in 2018 (%)**



Source: World Bank[10]

The electricity consumption in Angola reached 11.6 TWh, in 2020.[13] According to United Nations Statistics Division (UNSD) data, between 2014 and 2018 electricity consumption increased by 24 per cent. In 2018, households accounted for 59 per cent of total consumption and losses amounted to 12 per cent.[14] With uneven electrification, the consumption is concentrated in the northern region.[4]

The Regulatory Institute for Electricity and Water (IRSEA) was established in 2016 by Decree No. 59/16, transferring all rights and obligations from the Regulatory Institute for Electricity Sector (IRSE). The role of IRSEA is to regulate activities of production, transport, distribution, sale and use of electricity in the Public Electricity System (SEP) as well as to regulate the commercial relationship between SEP and agents that are not linked to it.[15] The design principles of this established model aim to develop a competitive process for both public and private generation and to establish an Independent Transmission Operator, which will also act as a single buyer for all electricity generated in the SEP.[4]

The electricity tariff categories are approved by Presidential Decrees No. 4/11 and No. 178/20 and defined by Executive Decree No. 122/19, which provides the basis for the calculation of tariffs. The rates are composed of two components, one based on the power and the other one based on consumption. The low voltage tariff rates are within the range of 2.46–14.74 AOA/kWh (0.004–0.026 USD/kWh), medium voltage rates are 9.61–11.54 AOA/kWh (0.017–0.020 USD/kWh) and the high voltage rate is 7.31 AOA/kWh (0.013 USD/kWh) (Table 1).[15]

Table 1. **Electricity Tariffs in Angola**

Category	*Power component (AOA (USD) per unit)*	*Consumption component (AOA (USD) per kWh)*
Low voltage		
Social household I	0	2.46 (0.004)
Social household II	80.00 (0.140)	6.41 (0.011)
Street lighting	45.00 (0.080) x pc	7.05 (0.012)
Single-phase household	90.00 (0.160) x pc	10.89 (0.019)
Three-phase household	100.00 (0.180) x pc	14.74 (0.026)
Commerce and services	100.00 (0.180) x pc	14.74 (0.026)
Industry	100.00 (0.180) x pc	12.82 (0.023)
Medium voltage		
Commerce and services	160.00 (0.280) x P	11.54 (0.020)
Industry	160.00 (0.280) x P	9.61 (0.017)
High voltage		
Industry	115.00 (0.200) x P	7.31 (0.013)
Distributors	115.00 (0.200) x P	7.31 (0.013)

Source: IRSEA[15]

Note: pc — contracted power (kVA), P — the maximum point of 15 consecutive minutes (kW).

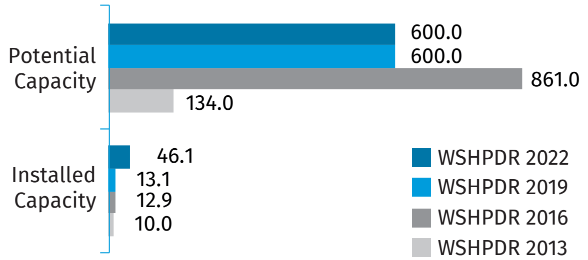
Presidential Decree No. 256/11, defining the National Policy and Strategy for Energy Security, established goals for the electricity sector until 2025.[16] For its implementation, short-term plans were defined. The plan for 2013–2017 fell short of what was initially planned. The following, 2018–2022 action plan has three development programmes and subprogrammes, which include the expansion of electricity access in urban areas, municipalities and rural areas; the optimization and sustainable management of the electricity sector; and private participation in the production and distribution of electricity.[4,11]

SMALL HYDROPOWER SECTOR OVERVIEW

The common definition of small hydropower (SHP) in Angola is up to 10 MW, although plants of up to 50 MW are often referred to as SHP as opposed to large hydropower of up to 1,000 MW and 2,000 MW. The installed capacity of SHP in Angola amounts to 46.1 MW (Table 2), indicating a significant increase since the *World Small Hydropower Development Report (WSHPDR) 2019* (Figure 4). The estimated potential capacity, as identified by the Angola Energy Strategy 2025 of the Ministry of Energy and Water (MINEA), is 600 MW from 100 different sites.[18] A list of known planned SHP projects is presented in Table 3.

Figure 4 presents a summary of SHP data made available by the National Water Resources Information System (INRH) and the Public Electricity Production Company (PRODEL-EP).[19,20] However, this list has not been updated since the publication of the *WSHPDR 2019*, providing the same estimate of SHP installed capacity of 13.1 MW as reported in the previous edition. Additionally, it is also known that ENDE manages SHP plants of up to 5 MW each, with a total installed capacity of 33 MW.[11] The sum of these two figures gives the installed capacity of 46.1 MW. The significant increase in SHP installed capacity since the previous edition of the report may be related to the uneven dispersion of information, in addition to the new investments made in this sector.

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Angola (MW)**



Source: *WSHPDR 2019*,[4] Gesto,[11] National Energy Atlas,[18] INRH,[19] PRODEL-EP,[20] *WSHPDR 2013*,[21] *WSHPDR 2016*[22]

Note: Data for SHP up to 10 MW.

Angola has a significant hydropower potential. However, the development and rehabilitation of power plants have not succeeded in keeping the supply in line with the expanding demand. The technical potential is estimated at approximately 80 TWh/year and the economic potential is 72 TWh/year (18 GW). Information on SHP potential in the country was assembled in the Atlas of the Hydropower Resource.[15,18,23]

The national plan for the electricity sector up to 2025 intends to develop new SHP plants for achieving the renewable energy installed capacity targets and to promote electrification of isolated rural areas.[15] From the 100 potential locations identified for SHP by MINEA, seven were selected with potential to supply nine municipal townships through isolated systems, including the Cutato, Quedas de Kaquina and M'Pupa Rapids SHP plants.[15,24,27] The 2025 Angola Power Sector Long-Term Vision lists the priority investments for the 2018–2025 horizon, with several potential SHP projects identified for priority investment (Table 4). Other potential sites not identified in the long-term vision also remain available for SHP development (Table 5).

RENEWABLE ENERGY POLICY

The Electricity Sector Transformation Programme (PTSE) is a result of the National Policy and Strategy for Energy Security and is divided into four implementation phases, the latest being over the period 2021–2025. It proposed a power sector reform involving three different measures: diagnosis, mobilization and change management; electric sector restructuring; and operational and functional improvement of public companies, implemented from 2012 to 2016. The studies conducted by this programme also recommend the incentivized participation of the private sector in renewable energy development in rural areas via feed-in tariffs and a partial liberalization of distribution systems and the energy sector, including full participation of independent power producers (IPPs) and the improvement of the energy mix.[4,25,28] This is proposed to be implemented until 2025.[28] Recently, in 2021, a law was established for independent energy production.

The restructuring of the electricity sector began in 1996, with the publication of the General Electricity Law 14-A/96, which, together with the Energy Security Policy of 2011, paved the way for the publication of new regulations essential for the energy market, and the amendment of the General Electricity Law, Law No. 27/15. Laws and Regulations published to establish the legal regime for the exercise of the activities of generation, distribution and supply of electricity, including by IPPs, are:

- General Electricity Law No. 14-A/96;
- General Electricity Law No. 27/15;
- Electricity Production, Transport, Distribution and Commercialization Activities Regulation, Presidential Decree No. 76/21;
- Electricity Supply Regulation, Presidential Decree No. 27/01;
- Regulation of Independent Electric Energy Production, approved by Presidential Decree No. 43/21;
- Regulation on the licensing of facilities for the use of electricity, Presidential Decree No. 40/04;
- Regulation of Electricity Production, Transport and Distribution facilities, Presidential Decree No. 41/04;
- Private investment law, Presidential Decree No. 10/21.[15,26]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

In early 2021, some changes were made in the regulatory framework of Angola which encourage the renewable energy sector, namely Decrees No. 76/21 and 43/21.[15] Furthermore, the Government of Angola has a specific decree for the model of concession contracts and the purchase and sale of electricity for SHP projects (No. 82/10). This is a legal instrument for public-private partnerships, aiming at the launch of the public tender for SHP and associated transport systems, as part of MINEA's intention to promote access to electricity in the isolated locations of the country.

The high-potential SHP sites identified under the Angola Energy Strategy 2025 programme are to be further studied. These feasibility studies aim to launch tenders for a total of 100 MW in mini- and small-scale hydropower projects.[17]

COST OF SMALL HYDROPOWER DEVELOPMENT

The mean cost of SHP installed in Angola is estimated at approximately 6.2 million USD/MW (Table 6), with the values being based on the Angola Energy 2025 strategy.[18]

Table 6. **Estimation of Small Hydropower Development Costs in Angola**

Andulo	6.20
Kuito 2	6.17
Kuando	6.20
Liapeca	6.20
M'Bridge	6.17
Cuemba	6.20

Source: MINEA[18]

FINANCIAL MECHANISMS FOR SMALL HYROPOWER PROJECTS

The Angola action plan for the energy sector 2018–2022 mentions that the main sources of financing of energy sector projects are: the Public Investment Programme (ordinary revenue of the treasury or the external and internal funding); revenues and financing of companies in the sector; or private investment with contingency guarantees.[11] Some policies are planned to be defined in Angola, including financial incentives, such as:

- Agreement for power purchase (PPAs) with feed-in tariffs over a reasonable period of time;
- Setting rates of return-on-investment for capital;
- Tax reductions (e.g., on income tax and imports).

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The climate projections predict a continuous temperature increase of approximately 2 °C from 2040 to 2059. This increase will lead to a rise of evaporation and evapotranspiration. The loss of water by evaporation in a reservoir can reduce the attractiveness of storage SHP plants. Besides, climate change will globally decrease mean annual precipitation by approximately 13 mm in the same timeframe. The impact that increased temperature and evapotranspiration may have on runoff is yet uncertain and must be closely monitored since it may reduce the availability of water for SHP operation.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

There are still several barriers to SHP dissemination in Angola, including:

- Limited experience of developing energy projects with private investors, as IPPs under Build–Operate–Transfer (BOT) or similar arrangements, as well as in the form of public-private partnerships;
- Lack of stability in the rule of law and governance, for asset ownership, concession award and return, land acquisition, claim management, power purchase/selling and unpaid bills retrieval;
- Deficient long-term financial models for providing affordable renewable energy to customers;
- Limited availability of technologies for mini, micro- and pico-hydropower;
- Fragile operation and management framework, regarding norms and standards and human resources capacity;
- Power purchase agreements priced in the local currency.[4,29]

Nonetheless, there are also several enablers to SHP development in the country:

- Political will to facilitate investment in the energy sector;
- Favourable topography and water availability for SHP development;
- Increased presence of international financial institutions following the peaceful transition in presidential power in 2017.

Cameroon

Joseph Kenfack, National Advanced School of Engineering

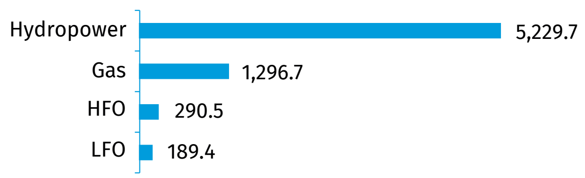
KEY FACTS

Population	27,224,262 (2021)[1]
Area	475,440 km^2
Topography	Four geographical regions can be distinguished in Cameroon. The northern region is occupied by a savannah plain sloping down towards the Chad Basin. The central region is a transitional area between the western and northern regions and is dominated by the Adamawa Plateau at 900–1,500 metres above sea level. The north-western region consists of volcanic mountains reaching over 2,400 metres, with Mount Cameroon (4,095 metres) being the highest point in the country. Finally, the west is occupied by lowlands reaching up to 600 metres above sea level.[2]
Climate	The climate differs between the north and the south of the country. In the south there are two dry seasons, in November–March and in June–August, with mean temperatures ranging between 22 °C and 29 °C along the coast. In the north, the dry season lasts from October to March and temperatures range from 23 °C to 26 °C.[3]
Climate Change	Climate change has significantly affected Cameroon and disrupted weather and precipitation patterns, making trend predicting more complex. The observed effects include more frequent extreme weather conditions, false starts to seasons, heavier rainfall and as a result floods as well as recurrent droughts, which, in turn, have resulted in the advancement of the desert. These impacts are expected to become more severe as global warming continues. By 2100, the average annual temperature is predicted to see a 1.5–4.5 °C increase depending on the region.[4]
Rain Pattern	The average precipitation varies from 500 mm to approximately 3,000 mm, peaking at 10,000 mm at Mount Cameroon.[5]
Hydrology	In the south of Cameroon, water flows towards the Atlantic Ocean or the Congo River catchment via the Sangha River and in the north, towards the Benoue River or Lake Chad. Thus, the river system can be broken down into four subsystems of different sizes. The Atlantic catchment is the largest of the four subsystems, with the Sanaga River alone draining a catchment area of 135,000 km^2 and having a plurennial flow reaching 2,000 m^3/s at Edea. The Sangha catchment includes three tributaries of the Sangha River, i.e., the Dja, Boumba and Kadei. The Sangha in its turn is a tributary of the Congo River. The Benoue River, forming the Benoue catchment area, is the largest of the Niger River's tributaries with a plurennial flow of 250 m^3/s. The tributaries of Lake Chad include the Vina and Mbere. Both rivers form the western branch of the Logone, which runs into the Chari that feeds Lake Chad.[6]

ELECTRICITY SECTOR OVERVIEW

Total electricity generation in Cameroon in 2019 was approximately 7,006 GWh, of which hydropower accounted for almost 75 per cent, gas for almost 19 per cent, heavy fuel oil (HFO) for 4 per cent and light fuel oil (LFO) for almost 3 per cent (Figure 1).[7]

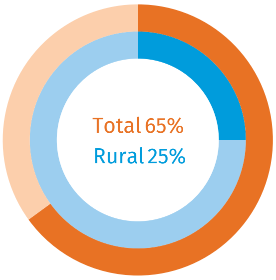
Figure 1. **Annual Electricity Generation by Source in Cameroon in 2019 (GWh)**



Source: Eneo[7]

The country's installed capacity is 1,547.3 MW, with hydropower accounting for 950 MW.[8] Hydropower is the main source of electricity generation. There are also several thermal power plants sustaining generation in grid-connected areas as well as operating off-grid. There are no electricity imports or exports, however, there are plans to connect Cameroon with Chad and Nigeria to mitigate the high cost of electricity generation in these countries. In 2020, the national electrification rate in Cameroon was nearly 65 per cent and the rural electricity access rate was 25 per cent (Figure 2).[9,10]

Figure 2. **Electrification Rate in Cameroon in 2020 (%)**



Source: World Bank[9,10]

The Ministry of Water and Energy (MINEE) and the Electricity Development Corporation (EDC) oversee the energy sector in Cameroon. The Rural Electrification Agency (AER) promotes rural electrification and the Electricity Sector Regulation Agency (ARSEL) approves electricity tariffs and determines electricity standards. The utility company Eneo is in charge of electricity generation and distribution, while the National Electricity Transport Company (SONATREL) manages the electricity transmission network. Cameroon has three main independent grids: the southern, eastern and northern grids. The electricity sector has been privatized since 1998. Kribi Development Corporation (KPDC), Dibanba Development Corporation (DPDC) and Memve'Ele are the most important generation companies outside Eneo. Nachtigal Hydro Company (NHPC) is constructing a 420 MW hydropower plant and will be the biggest generation company after Eneo.

After commissioning the first small hydropower (SHP) plants in the early 1930s, Cameroon switched to large-scale hydropower development, with a number of plants commissioned in the late 1980s. For several decades, no new hydropower plants were commissioned in Cameroon due to an unfavourable economic situation. Nonetheless, hydropower remains the main source of electricity generation in the country. However, there are also plans to develop large-scale solar power plants to reduce the currently high use or thermal power. The development of SHP can also have a high positive impact on the country, especially in rural and remote areas that experience such issues as high voltage drops due to the long distances of transmission and regular power shortages from selective power cuts or the aging medium-voltage network. Overall, in a developing country such as Cameroon, electricity demand is always on the rise (estimated to grow at an average annual rate of 4 per cent until 2040), to the point that the development of energy infrastructure does not manage to keep up, leading to selective power cuts even in large cities.[11]

The role of foreign investment is crucial for the development of the electricity sector in Cameroon. The ongoing generation projects are mainly funded through foreign funds as the national banking system provides very limited support to investment in the sector due to high interest rates.

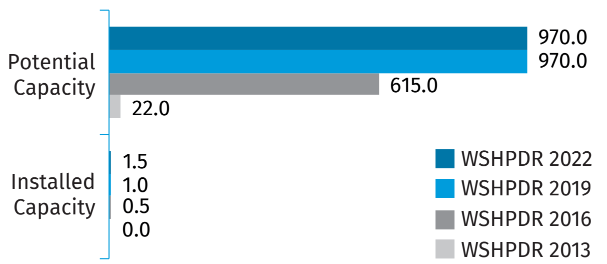
The electricity tariff system has remained unchanged since 2012. The rates are uniform all over the country and do not vary throughout the year but depend on the voltage level and the amount of energy consumed. Domestic consumers pay between 50 CFA/kWh and 99 CFA/kWh (0.077–0.150 USD/kWh).[12] Current tariffs do not represent the actual cost of electricity generation and are heavily subsidized by the Government.[13]

SMALL HYDROPOWER SECTOR OVERVIEW

There is no official definition of SHP in Cameroon, however, there is a specific regulation for power plants of up to 5 MW for rural electrification. For the purposes of this chapter, the standard up to 10 MW definition will be followed.

In 2021, the 1.48 MW Mbakaou SHP plant was commissioned (Table 1), increasing the installed SHP capacity in the country compared to the *World Small Hydropower Development Report (WSHPDR) 2019*.[14] The Mbakaou plant became the first SHP plant to be developed in the country in decades and there are plans to further boost the SHP sector. The plants developed in the early 1930s were abandoned because of the grid extension from large-scale plants, but could be rehabilitated. There might also exist other smaller-scale plants developed by non-governmental organizations, such as the 20 kW plant in Tchouadeng, however, there is no accurate information on their installed capacity and operational status.[15] The total potential is estimated at 970 MW and remains unchanged compared to the previous edition (Figure 3).[16]

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Cameroon (MW)**



Source: Afrik21,[14] *WSHPDR 2019*,[16] *WSHPDR 2013*,[17] *WSHPDR 2016*[18]

A detailed assessment of the SHP potential in the country is yet to be carried out, however, new SHP projects are most needed in the mountainous areas where the network experiences high voltage drops. One project under development is the 2.9 MW Ngassona plant (Table 2).

RENEWABLE ENERGY POLICY

The climate change policy is monitored by the Ministry of Environment in collaboration with other institutions. The Government's policies regarding renewable energy are being enhanced by new regulations under preparation, including plans and programmes relevant to SHP, especially the funds for feasibility studies.

According to the National Development Strategy 2020–2030, the country's total installed capacity is to reach 5,000 MW by 2030. The energy mix is to be based on hydropower, solar photovoltaics, gas-based thermal power and biomass. In the hydropower sector, the focus is on large-scale projects that are to be realized via public-private partnerships (PPP) or independent production. However, the Government will also encourage the construction of mini-scale hydropower to meet household demand for electricity. Legislation aimed at stimulating domestic private investment in such projects is to be developed.[19]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

SHP is governed by the same regulations as the entire electricity sector. However, specific government plans and programmes targeting SHP are highlighted in the framework for rural electrification, especially for capacities below 5 MW. There are plans to review the legislation and regulations related to titles awarded to new plants, including SHP plants. The licensing process for SHP plants is the same as for other technologies and requires all documents from the feasibility studies, including the environmental impact assessment (EIA).

COST OF SMALL HYDROPOWER DEVELOPMENT

The total cost of the Mbakaou SHP project was approximately USD 6.9 million.[20]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

While subsidies and other incentives and forms of financial support can be obtained from the Government, SHP projects usually rely on foreign funds. Many international institutions are willing to fund the development of SHP in Africa, including Cameroon.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Despite the large potential and the strong will of the Government, the development of the SHP sector has been very limited so far. The key barriers to SHP development include:

- Lack of a detailed assessment of SHP potential;
- Lack of funds for SHP development;
- Need for capacity building;
- Lack of mature projects;
- Unreliable infrastructure;
- No local production of electromechanical equipment.

The key enablers for SHP development are:

- Great SHP potential,
- SHP can provide a solution to grid unreliability in rural areas;
- Liberalized sector;
- Available grid code;
- Strong policy focus on renewable energy development, including SHP.

Central African Republic

Pedro Manso and Mathieu Barnoud, MHYD water & energy solutions sàrl

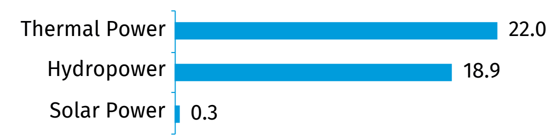
KEY FACTS

Population	4,745,185 (2019)[1]
Area	623,000 km^2 [2]
Topography	The Central African Republic is a landlocked country. The lowest point in the country is the Oubagui River at 335 metres above sea level, while the highest point is Mount Kayagangiri at 1,420 metres above sea level. Rolling hills cover the centre and the south of the country. The south-east is occupied by a dense tropical forest, while the northern part of the country is flat, similar to a savanna.[3]
Climate	The climate in the Central African Republic is warm, equatorial and humid, and has defined rainy and dry seasons. Temperatures vary between 19 °C and 30 °C during the wet season, from May to October, and range from 18 °C to 40 °C in the dry season, from November to April.[4]
Climate Change	Future climate scenarios indicate a temperature increase on the order of 1.4-2.2 °C, assuming low greenhouse gas emissions, and 1.8-2.7 °C, assuming high emissions. The probability of extreme climatic hazards occurring could increase with climate change, with the main hazards consisting of heavy rains followed by floods and droughts.[4]
Rain Pattern	Heavy rainstorms frequently occur during the rainy season (May–October). Maximum annual precipitation can reach up to 1,800 mm. In the Karre Mountains the average rainfall is estimated at 1,500 mm. The north of the country is drier than the south. The average annual precipitation across the country is 1,373 mm.[4,5]
Hydrology	There are important waterways harmoniously distributed across the territory of the Central African Republic. In the north of the country, the Chari River tributaries flow. The Ubangi River is one of the most iconic in the country, forming the southern border with the Democratic Republic of the Congo. The river has numerous tributaries, such as the Chinko, Kotto, Lobaye, Mbari and Ouaka. The Mbomou River (or Bomu) represents the Ubangi River’s headstream, flowing 725 km towards the west, and also contributes to forming the border with the Democratic Republic of the Congo.[4]

ELECTRICITY SECTOR OVERVIEW

The total installed capacity of the Central African Republic in 2019 was approximately 41.2 MW, including 22.0 MW of thermal power capacity, 18.9 MW of hydropower and 0.3 MW of solar power (Figure 1).[6]

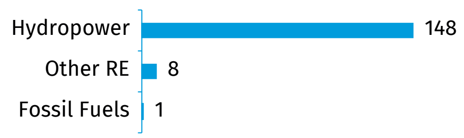
Figure 1. **Installed Electricity Capacity by Source in the Central African Republic in 2019 (MW)**



Source: African Energy Portal[6]

Gross electricity production was estimated at approximately 155 GWh at the end of 2018, and reached 157 GWh in 2019. Roughly 148 GWh were produced by hydropower in 2019, 8 GWh came from other renewable energy sources, and 1 GWh from thermal power plants (Figure 2).[7] Transmission losses are estimated at 7 per cent of the electricity produced in 2017, while distribution losses amounted to 33 per cent, which is higher than the average across Sub-Saharan Africa (between 18 and 20 per cent).[8]

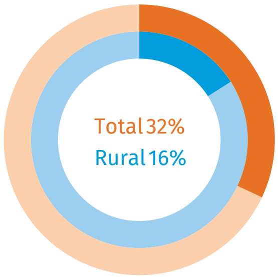
Figure 2. **Annual Electricity Generation by Source in the Central African Republic in 2019 (GWh)**



Source: AFREC[7]

Total access to electricity in the country reached 32 per cent at the end of 2019, indicating a three-fold increase since 2010.[9] However, access to electricity is unequally distributed between urban and rural areas. Thus, 55 per cent of the urban population had access to electricity in 2019 against 16 per cent of rural population.[9]

Figure 3. **Electrification Rates in the Central African Republic in 2019 (%)**



Source: World Bank[9]

Currently, the electricity supply in the Central African Republic remains lower than the demand. Furthermore, demand forecasts for the coming years predict a growth in peak demand from 80 MW in 2010 to 403 MW in 2030 in the low-growth scenario.[10]

The Ministry of Development for Energy and Water Resources (MDEWR) oversees the electricity sector in the country, with a Directorate General for Electricity established as part of the Ministry. The entity in charge of electricity production, transport and distribution is Energie Centrafricaine (ENERCA), which is a public organization founded in 1963 and owned by the Government. The two other main agencies in the Central African Republic are the Rural Electrification Agency (ACER) and the Autonomous Electricity Sector Regulatory Agency (ARSEC).[8]

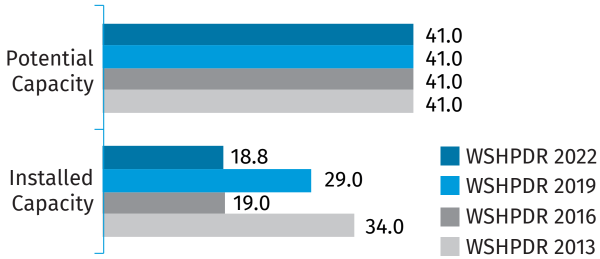
Hydropower in the country is delivered to the capital city of Bangui by two transmission lines with 17.5 MVA and 35 MVA of transit capacity. Losses in the electricity transmission and distribution system are high, due to the age of the facilities and difficulties to carry out adequate maintenance.[10]

Electricity tariffs are determined by cumulative hours of usage per month. The mixed tariffs for low-tension consumers in 2021 were 0.13 USD/kWh for usage of up to 65 hours, 0.14 USD/kWh for up to 130 hours and 0.15 USD for over 130 hours of usage. Mid-tension tariffs range from 0.044 to 0.070 USD/kWh.[11] Access to electricity in small cities and rural areas is very limited due to the price gap and the lack of infrastructure. To cover investment and operational expenses, the average electricity price should be approximately 0.2 USD/kWh.[12] This price difference induces a deficit of approximately USD 7 million per year (0.4 per cent of Gross Domestic Product).[12] The higher tariff needed is due mainly to losses in transportation and distribution as well as losses related to invoice collection and overstaffing, which are the highest in Africa, and represented 48 per cent of the budgetary deficit in the energy system in 2014.[12]

SMALL HYDROPOWER SECTOR OVERVIEW

The small hydropower (SHP) definition in the Central African Republic refers to plants of up to 10 MW. As of 2021, the total installed capacity of SHP in the country was 18.75 MW, made up of two plants: Boali I (8.75 MW) and Boali II (10.00 MW) (Table 1). It is estimated that Boali I could reach an additional capacity of up to 9.5 MW through rehabilitation works.[13] A further 10 MW was scheduled for the Boali III plant, which never was commissioned due to political instability in the country. At the current state, the Boali III plant is not complete and cannot produce electricity without a rehabilitation (dam monitoring and electro-mechanical devices). As a result of this, the total installed SHP capacity figure has decreased since the *World Small Hydropower Development Report (WSHPDR) 2019*, which counted the Boali III plant as operational. The potential estimate remains unchanged as no new data were made available (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in the Central African Republic (MW)**



Source: *WSHPDR 2013*,[14] *WSHPDR 2016*,[15] *WSHPDR 2019*,[16] Manso & Barnoud[17]

Table 1. **List of Operational Small Hydropower Plants in the Central African Republic**

Name	*Location*	*Capacity (MW)*	*Head (m)*	*Plant type*	*Operator*	*Launch year*
Boali I	M'bali River	8.75	52	Run-of-river	ENERCA	1955–1969
Boali II	M'bali River	10.00	64	Run-of-river	ENERCA	1976

Source: International Journal on Hydropower & Dams[13]

Potential for SHP development in the country exists in the following locations: Baboua, Bambari, Bangassou, Berbérati, Bocaranga, Bossangoa, Bouar, Bria, Carnot, Kaga-Bandoro, Kembe, Mbaîki, Ndélé, Paoua and Sibut.[18] The SHP potential is estimated at 41 MW as was reported in the previous editions of the *WSHPDR*. Additionally, 30 sites suitable for development of hydropower plants of varying sizes were identified, with capacities between 0.5 MW and 180 MW.[19] However, the site names are not known.

The United Nations Development Programme (UNDP), in collaboration with the Global Environment Facility (GEF), attempted to develop electricity generation capacities and encourage investment in Western and Middle Africa, including the Central African Republic. The project aimed to develop 36 SHP plants in the region, alongside creating an SHP network. However, in 2011 the project was cancelled for the entire region due to regional political instability.[20]

Table 2. **List of Planned Small Hydropower Projects in the Central African Republic**

Name	*Location*	*Capacity (MW)*	*Head (m)*	*Plant type*	*Developer*	*Planned launch year*	*Stage of development*
Boali III	M'bali River	10	~30	Reservoir	ENERCA	–	Feasibility study
Boali I bis	M'bali River	–	–	Run-of-river	–	–	Feasibility study
Boali II bis	M'bali River	10	64	Run-of-river	China Gezhouba Group Corporation (CGGC)	2022?	Under construction

Source: ENERCA[10]

The incomplete Boali III plant includes an embankment dam approximately 30 metres in height and 780 metres in length. The plant is located in the central concrete block of the dam between the overflow spillways, but has never been commissioned. The dam monitoring ceased in 2010. The dam is only used, at the current time, for water flow regulation for the hydropower cascade formed by the Boali I and Boali II plants downstream. Commissioning Boali III would allow adding up to 7.5–10.0 MW of capacity without an additional territorial footprint. A preliminary safety assessment was carried out in 2019 and revealed dam security and monitoring deficiencies. In the meantime, emergency measures have been recommended and further studies have started. It can already be stated that Boali III will need large civil and electro-mechanical works in order to put the 10 MW plant in operation and to secure water storage for the entire SHP cascade of Boali I, II and III.

A new power plant named Boali II bis is presently under construction next to the existing Boali II plant. Another new project called Boali I bis is planned downstream from the existing Boali I plant, but investment for it has not been yet secured.

In addition, ENERCA plans to develop small, mini- and micro-hydropower plants for a total of 40 MW before 2030. Additionally, also some larger hydropower plants (> 10 MW) are to be developed (Lobaye, Dimoli, Lancrenon, Kotto).[10] There are also plans to provide power supply to areas in the Central African Republic from the future Mobayi SHP plant in the neighbouring Democratic Republic of the Congo.[21]

RENEWABLE ENERGY POLICY

The Central African Republic aims to reduce its emissions by at least 5 per cent and 25 per cent by 2030 and 2050, respectively, compared to its baseline emissions in the business-as-usual scenario for both years.[22] The country also aims to reduce emissions of short-lived climate pollutants, which have a significant short-term global warming potential and harmful effects on health, agriculture and ecosystems. In addition, the entire national territory is exposed to extreme climatic hazards such as droughts and heavy rains followed by flooding. The Government aims to strengthen the country's resilience to climate change in key sectors.[22]

The Central African Republic envisages a holistic approach to climate change mitigation by integrating the adjustment of national policies and strategies, the improvement of legislative and regulatory frameworks, the development of capacities and technology transfers in certain priority areas. The following energy sources are being encouraged:

- Small and micro-hydropower plants;
- Solar thermal and photovoltaic energy;
- Processes for the methanization of organic matter;
- Improved carbonization.[22]

Apart from micro-hydropower plant development, the construction of a solar power plant at Bangui, a 72 MW hydropower plant at Lobaye, a 180 MW hydropower plant at Dimoli and the Mobayi hydropower plant is also planned in the next 15 years.

Micro-hydropower and solar power are the key targeted technologies, while most renewable energy sources, such as wind and geothermal power, are still widely unexplored in the country.[22] There is existent potential for the geothermal energy, however, no studies were conducted to determine it. Wind speed measurements show promising potential at above 5 m/s and, therefore, wind power could also be a viable alternative for electricity generation in the country. The high costs associated with the development of solar power might limit its use in the Central African Republic to certain applications or services.[23]

The economic reforms initiated by the Government to encourage private investment in the Central African Republic have led to the following framework document set:

- Law No. 01.10 of 16 July 2001, instituting a charter of investments in the Central African Republic;
- Ordinance No. 05.001 of 1 January 2005 on the Electricity Code of the Central African Republic;
- Decree No. 010.092 of 18 March 2010 defining the National Energy Policy.

These instruments provide a framework for investment in the energy sector but above all offer investors the means to implement their projects.[10]

There is no specific legislation or regulation for SHP.

COST OF SMALL HYDROPOWER DEVELOPMENT

No consolidated estimates of the average cost for the development of SHP in the Central African Republic are available. Of the three small Boali plants, only the cost of Boali III can be found in open sources.[24] However, the 10 MW capacity of this plant has never been fully installed and put into operation, therefore, the cost per MW may not be relevant. Cost estimates of the largest hydropower plant projects planned over the next 15 years were used to obtain an estimate of the cost per MW of installed capacity in the Central African Republic. The average cost of hydropower installed capacity appears to be approximately 3.7 USD/MW (Table 3). Average cost of SHP development is unavailable.

Table 3. **Cost Estimation for Hydropower Plants in the Central African Republic**

	Project cost (USD million)	*Cost per unit of installed capacity (USD million/MW)*
Dimoli (180 MW)	275	1.5
Lobaye (72 MW)	180	2.5
Kotto (60 MW)	500	8.3
Boali III (10 MW)	25	2.5
Average		**3.7**

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

Nowadays, the Central African Republic remains dependent on multilateral funding and donations (World Bank, African Development Bank and United Nations Industrial Development Organization) as well as bilateral financing (European Central Bank, French Development Agency and Export-Import Bank of China). This is not always a reliable way of funding projects, as they may be cancelled due to political instability in the region.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The evolution of rainfall due to climate change varies greatly according to the scenarios, with some projecting a slight increase in annual rainfall, while others project irregular variations in precipitation. Furthermore, there are no comprehensive studies for the Central African Republic showing the potential impact of future rainfall variation on available river runoff. Temperature increases may induce larger evaporation and therefore the water balance of existing reservoirs must be reassessed, in particular that of Boali III, where the reservoir surface is large (40 km^2). Besides, the probability of occurrence of extreme climatic hazards could increase with climate change. The main hazards are heavy rains followed by floods and droughts.[25] Existing SHP plants as well as new projects will need to be rehabilitated or designed to be resilient to such hazards (as recommended by the International Hydropower Association).

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

There are multiple barriers to SHP development in the country. Some of the most important ones are the following:

- The strong monopoly in the electricity sector disincentivizes investors, increases the project-related costs and limits potential profit;
- Lack of feed-in tariffs and other support schemes for SHP development;
- Lack of trained staff able to ensure efficient operation, maintenance and management of SHP plants;
- Limited financial resources and political unrest might deter future investment in SHP;
- No standards for SHP are developed in the region, which makes current access to electricity from SHP generators unreliable and affects the prospects for future projects.[13,20]

However, due to its known benefits and potential, also efforts are being made to implement future SHP policies in the Central African Republic. The main enablers for SHP development are:

- Existing contact with organizations in the field facilitates the development strategy (ENERCA, ACER);
- Climate and topography are suitable for hydropower development;
- The will to develop SHP and rural electrification projects;
- Local presence of International Financial Institutions;
- An investment programme through ENERCA, including SHP development scheduled between 2016 and 2030.

Congo

Gilbert Nzobadila, African Energy Commission; Boniface Hervé Mabikana Voula, Ministry of Energy and Hydraulics1*

KEY FACTS

Population	5,518,000 (2020)[1]
Area	342,000 km[2]
Topography	The coastal area is a plain approximately 40 kilometres wide and 160 kilometres long between Gabon and Cabinda.[2] There are three dominant mountain ranges in Congo. The Mayombé Massif, or Mayumbe, is an old low-lying chain of mountains with deep river gorges that extends from the mouth of the Congo River in the south and to the Kouilou-Niari River in the north and parallels the coast.[2] The neighbouring Niari region hosts a valley and another mountain range, Chaillu Massif, reaching elevations of 400-700 metres above sea level before extending into south Gabon.[2] Beyond the Niari Valley lies a series of plateaus at approximately 490 metres. A vast plain occupies the north-eastern part of the country. The highest peak is Mont Nabemba (1,020 metres) located in the north-west.[2]
Climate	The climate in Congo is mostly hot and humid with heavy precipitation, due to the country's geographical location and the coastal plain. The north of the country has an equatorial climate, while the south has a tropical one. Average temperatures vary between 24 °C and 28 °C throughout the year.[3]
Climate Change	Congo is projected to see a 1 °C rise in mean annual temperatures by 2050 and to experience increased heat wave durations. The area will also see an increase in annual rainfall by 2046-2065 and an intensification of rainfall.[3]
Rain Pattern	Precipitation is abundant but varies throughout the year and across regions, with the equator crossing the country in the middle. The north of Congo experiences a dry season from November to April and a rainy season from April to November, whereas in the southern part the rainfall pattern is the exact opposite. Annual precipitation in the country averages 1,200 mm but often surpasses 2,000 mm. In the north, average annual precipitation ranges between 1,500 and 2,000 mm, while in the south precipitation can be lower than 1,500 mm and reach 1,200 mm near the coast.[2]
Hydrology	The major river is the Congo River. Its main northern tributary, the Ubangi River, flows southwards and forms the country's eastern border. The largest right-bank tributaries of the Congo River include the Sangha, the Likouala, the Alima, the Nkeni, the Lefini, the Djoue and the Foulakari.[2] The Kouilou-Niari is another major river that flows south-west from its source in the plateau region to Kayes and into the Atlantic. On the stretch from the Niari valley to Makabana it is known as the Niari River.[2]

ELECTRICITY SECTOR OVERVIEW

From 2018 to 2019, overall electricity generation in Congo increased by 5 per cent, however, most of this generation increase was made up by thermal power generation from the gas-fired Congo Power Plant (Centrale Electrique du Congo, CEC) Pointe-Noire (Figure 1).[4] In contrast, hydropower generation decreased by 22 per cent, from 1,120 GWh in 2018 to 872 GWh in 2019. This decrease mainly came from the Imboulou hydropower plant, whose generation in 2019 decreased by more than 30 per cent compared to 2018 (Table 1).[4]

Table 1. **Annual Electricity Generation by Power Plant in Congo in 2015–2019 (GWh)**

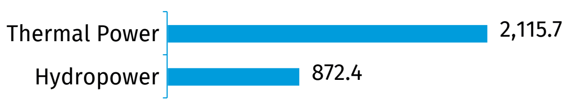
Power plant	*Installed capacity (MW)**	*Type*	*Annual generation (GWh)*				
			2015	*2016*	*2017*	*2018*	*2019*
Imboulou	120	Hydropower	703.5	684.4	702.8	645.3	433.1
Moukoukoulou	74	Hydropower	394.5	430.1	473.9	449.0	413.5
Liouesso	19	Hydropower	N/A	12.5	26.4	25.7	25.8
Djoué (non-operational since 2007)	15	Hydropower	-	-	-	-	-
CEC Pointe-Noir	484	Thermal power	1,434.5	1,643.5	1,646.7	1,719.2	2,115.3
Djeno (non-operational since 2018)	50	Thermal power	N/A	N/A	N/A	-	-
Brazzaville	32	Thermal power	4.8	2.2	2.0	3.0	0.4
Total	**794**		**2,537.3**	**2,772.7**	**2,851.8**	**2,842.2**	**2,988.1**

Source: E2C,[4] LCA,[5] ANDRITZ HYDRO,[6] E2C[7]

Note: *As of 2020.

As of February 2020, the installed capacity of Congo was at least 794 MW. Of this, thermal power accounted for approximately 71 per cent and hydropower for 28 per cent (Figure 2).[5,6,7] The renovation works of the gas-fired power plant CEC Pointe-Noire were completed in February 2020, increasing the plant's installed capacity to 484 MW and, therefore, the country's total installed thermal power capacity to 566 MW.[8] The total hydropower capacity is 228 MW, including the 15 MW of the non-operational Djoué plant. The largest hydropower plant in the country is the Imboulou plant of 120 MW, which came online in 2010 and supplies electricity to the city of Brazzaville. In addition to its domestic capacity, Congo imports 50 MW from the Inga hydropower plant in the Democratic Republic of the Congo (DRC).[5,6] The electricity grids of the DRC and the Republic of Congo are interconnected.

Figure 2. **Installed Electricity Capacity by Source in Congo in 2020 (MW)**

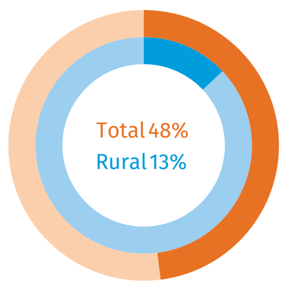


Source: LCA,[5] ANDRITZ HYDRO,[6] E2C[7]

More than half of the country's total installed capacity comes from the gas-fired power plant at Pointe-Noire (Table 1). The role of this plant is particularly important during the dry season when generation by hydropower plants decreases. The plant has three turbines, which have operated in parallel with the Inga hydropower plant in the DRC since 2015. The Government expanded the plant with the addition of a third 170 MW turbine. The two pre-existing turbines were at a capacity of 314 MW (each one was upgraded from 150 to 157 MW), bringing the total capacity of the plant up to 484 MW.[7] The work for this project commenced in 2019 and was completed on 18 February 2020.[8] The plant has the potential to reach up to 1 GW in the future with efficiency improvements and the addition of a proposed fourth turbine.[7] The Djeno thermal power plant has not been in operation since the transfer of its operating capacity to Kouilou Power SA in 2018.[9]

There are four hydropower plants in the country, however, only three of them are operational. In 2018, as part of the reforms undertaken in the sector, the Government launched the bidding for tenders for hydropower projects. The Djoué hydropower plant has not been functioning since 2007 due to flooding and subsequent rehabilitation work.[6] In 2018, Yunnan Linkun Investment Group agreed to rehabilitate the plant.[10] According to other sources, the task of completing a feasibility study and providing technical assistance for upgrading the power plant from 15 MW to 30 MW was awarded to Studio Pietrangeli Consulting Engineers.[11,14] It is unclear if any of this planned rehabilitation, extension and modernization work at the Djoué power plant is continuing as planned. The most recently constructed hydropower plant, the Liouesso plant, with a capacity of 19.2 MW, was commissioned in the northern Sangha Department on the Sangha River in 2017.[12] The installation of this plant aimed to foster economic activity in the region. Previously, users had access to electricity for only a couple of hours per day.[12]

Figure 3. **Electrification Rate in Congo in 2019 (%)**



Source: World Bank[13]

In 2019, 48 per cent of the country's population was connected to the electricity grid, and only 13 per cent in rural areas (Figure 3).[13] In comparison, 9 per cent of the rural population had electricity access in 2010, mostly due to access to mini-grids fuelled by diesel or gasoline.[14] The electricity demand of Congo has been growing and is expected to exceed 1 GW by 2027.[15] In particular, the demand of the Pointe-Noire special economic zone is expected to reach 700 MW, the demand of the city of Brazzaville 250 MW and the demand of the potash mines in Kouilou 150 MW.[15] With this in mind, the Government aims to increase the electricity generating capacity of the country.

The projects under development include the Chollet hydropower plant, with a capacity of 600 MW, which is to be jointly developed by Cameroon and Congo. The plant will be located in the Ngbala region of Congo on the Dja River and will make up part of the Central Africa Power Pool (CAPP). The project envisages the construction of electricity lines between the two countries and will interconnect their electricity networks. Congo will be the major beneficiary of the project, receiving 300 MW of the capacity, Cameroon will receive 60 MW and the remaining 240 MW will go to neighbouring countries. The contract on the construction of the plant was signed in 2010, however, little progress had been made until 2017 when the Intergovernmental Committee of the two countries met to confirm the intention to accelerate the development of the project.[16] Following another meeting in 2020, the technical and feasibility studies were scheduled to take place during the first quarter of 2021, after which the questions of financial mobilization and construction of the project are to be addressed.[17] Another project under consideration is the 80–100 MW hydropower plant of Mourala, on the Louessé River.[18] The feasibility study for the Mourala project has been completed and as of 2019 research for financing was underway.[19] A number of other potential hydropower projects are currently under consideration.[20]

On 9 April 2019, the Government of Congo and the Ministry of Energy and Hydraulics signed a memorandum of understanding with the China Railway 20th Bureau Group Co Ltd (CR 20GC) to develop the Gorges de Sounda hydropower project in the Kouiloi department.[21] The memorandum of understanding defined the manner in which the project will be implemented and that CR 20GC will lead the feasibility studies, including environmental and social impact reports, thereby completing preliminary studies undertaken by the International Finance Corporation (IFC). In November 2017, the IFC recommended a capacity between 486 MW and 616 MW and an optimal concept at a 70 metre full supply level, in consideration of the environmental and social impact of the project.[22,23] The studies performed by CR 20GC were expected to propose a higher capacity estimate than that proposed by the IFC study while minimizing the environmental and social impact. This new study is in response to the Government's aim to maximize the potential of the project and explore optimal options between 80 and 100 metres of full supply level.

The electricity sector of Congo is regulated by the Ministry of Energy and Hydraulics, and the National Agency for Rural Electrification (Agence Nationale d'Electrification Rurale, ANER) oversees the electrification of rural areas. In 2003 and after the creation of the Agency for the Regulation of the Electricity Sector (l'Agence de Régulation du Secteur de l'électricité, ARSEL), the sector was liberalized, legally ending the state-owned monopoly. However, a major role in the electricity market was still played by the state-owned company the National Electricity Company (Société Nationale d'Electricité, SNE), which was founded in 1967 through Law No. 67. SNE produced, transported, distributed and marketed electricity and maintained electrical infrastructure. After liberalization, it still held monopoly over electricity production until 2018.[24] The electricity sector opened up to private investors in 2018, and international financial institutions such as the International Monetary Fund and the World Bank have supported privatization, competition and economic reforms in the sector.[22]

In February 2018, the Government approved the plan to dissolve the SNE as well as the National Water Distribution Company (Societe Nationale de Distribution d'Eau, SNDE) since they proved to be inefficient and failed to reach sufficient profitability despite state investment. Following the sector reforms, the Heritage Company for the Electricity Sector (Société de Patrimoine pour le secteur de l'électricité, SPSE) was created. The creation of two other government agencies also ensued: the Society for Electricity Transportation (La Société de Transport de l'électricité, STE) and the Heritage Society for the Water Sector (La Société de Patrimoine pour le Secteur de l'Eau, SPSEA), which manage the sector based on public service concession contracts between the Government and public and private operators.[25] As of 2021, CEC S.A. is the main electricity producer, owned 20 per cent by ENI and 80 per cent by the state, and operates independently after attaining a licence from the Ministry of Energy and Hydraulics.[24] The reform of the electricity sector is expected to attract investment into the sector, and boost the struggling economy.[27]

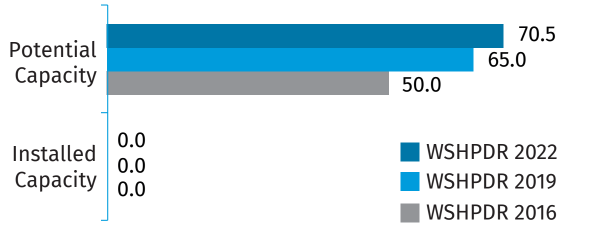
Electricity in Congo is transmitted via 110 kV and 220 kV lines and distributed via 30 kV, 20 kV, 6.6 kV, 380 V and 220 V lines. Following Decree No. 681 of 19 March 1994 by the Ministry of Commerce, Consumption and Small and Medium Enterprises, electricity tariffs in Congo have been unified across the country and divided into three categories: low voltage, public lighting and medium and high voltage. Electricity prices vary depending on these three categories and the level of consumption regardless of the type of consumer. Low voltage tariffs vary between 31.2 XAF/kWh (0.019 USD/kWh) and 49.08 XAF/kWh (0.030 USD/kWh).[28] Small producers outside of the national grid may negotiate prices with the consumers, according to Article 20 of the National Electricity Code.[14]

SMALL HYDROPOWER SECTOR OVERVIEW

There is no official definition of small hydropower (SHP) in Congo, therefore, this report uses the standard definition of SHP as hydropower plants with a capacity of up to 10 MW.

At present, Congo has four large hydropower plants. The smallest plant is at a capacity of 19.9 MW, the Liouesso plant, was commissioned in 2017 and constructed by the China Gezhouba Group.[29] The potential for hydropower development in the country has been estimated at approximately 14 GW, as defined by Government Decree No. 2010-822 of 31 December 2010.[29,30] The technical potential has been estimated at 3.9 GW, of which approximately 4 per cent has been developed.[25] The main potential for hydropower development is located in the Plateaux region, the Sangha region, Cuvette and Cuvette-Ouest. The potential for SHP development is assumed to be quite significant, but there are no publicly available feasibility studies and no ongoing SHP projects in Congo at this time. Compared to the results of the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed SHP capacity has not changed and stayed at zero, whereas the potential capacity increased by 9 per cent due to revised calculations (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2016/2019/2022 in Congo (MW)**



Source: *WSHPDR 2013*,[33] *WSHPDR 2016*,[34] *WSHPDR 2019*[35]

A Global Environment Fund–funded United Nations Development Programme (UNDP) project, Small Hydropower-based Mini-grids for Rural Electrification in Congo-Brazzaville, is planning 12 feasibility studies, but the project was still in its infancy as of 2019 and faced technical setbacks due to management and satellite data interruptions.[31]

The Hydropower Atlas developed by the UNDP in 2008 identified 17 potential SHP sites with capacities ranging between 6 kW and 6 MW and a combined capacity of almost 21 MW (Table 3).[18] Another study identified 10 potential sites with estimated capacities ranging between 5 MW and 10 MW with a combined capacity of at least 50 MW.[31] Based on these two estimates, the potential of SHP in Congo should be at least 70.5 MW. An additional feasibility study of seven potential mini-hydropower sites was proposed by the African Development Bank, and six feasibility studies are currently underway under the African Development Bank's Light up and Power Africa programme and expected to be approved for 2021.[32]

Although SHP could be used to meet the needs for electricity in rural areas as well as feed into the national grid, serving as an efficient and environmentally sustainable source, the sector has faced numerous barriers hindering its development. The gaps in the regulatory framework in relation to SHP projects, the lack of local skills to install, operate and maintain an SHP plant as well as of local technology make the sector less attractive than other power projects.[14] Another major barrier is low electricity tariffs.[34]

SMALL HYDROPOWER PROJECTS AVAILABLE FOR INVESTMENT

Table 2 offers details on SHP projects available for development in the country.

Table 2. **List of Selected Small Hydropower Sites Available for Development**

Name	*Location*	*Potential capacity (MW)*	*Head (m)*	*Type of site (new/refurbishment)*	*Type of project*
Mambouana	Lekoumou	0.43	424	New	Run-of-river
Assoumoundele	Sangha	6.18	202	New	Reservoir
Kimpanzou	Pool	5.51	380	New	Run-of-river
Kimbanda	Pool	4.02	250	New	Dam
Bela	Pool	3.18	260	New	Reservoir

Note: Data from 2008.

RENEWABLE ENERGY POLICY

The Government envisages the development of renewable energy sources available in the country, including hydropower, biomass, solar power and wind power, in particular in remote areas. However, no policy or strategy promoting renewable energy has been developed to date. As a result, the available resources remain untapped.

The major laws and regulations of the electricity sector include:

- Law No. 14/2003 of 10 April 2003, defining the Electricity Code and liberalizing the market;
- Law No. 15/2003 of 10 April 2003, establishing the National Agency for Rural Electrification (ANER);
- Law No. 16/2003 of 10 April 2003, establishing the Agency for the Regulation of the Electricity Sector (ARSEL);
- Law No. 17/2003 of 10 April 2003, establishing the Development Fund of the Electricity Sector;
- Decree No. 2010-822 of 31 December 2010, approving the development strategy for the sectors of electricity, water and sanitation;
- Law No. 22-2018 of 13 June 2018 establishing the dissolution of the National Electricity Company (SNE);
- Decree No. 295-2018 creating the new Electrical Energy Society of Congo (Société Energie Electrique du Congo, E2C).

In accordance with the Electricity Act of 2013, independent power producers are required to obtain a licence. However, for small-scale projects of electricity generation, transmission, distribution and sales in rural areas, it suffices to obtain an authorization by the corresponding Ministry. Every project within the electricity sector is obliged to conduct an environmental impact study prior to the commencement of the project, according to Article 12 of the national Electricity Code. Financial incentives for the sector are non-existent.

COST OF SMALL HYDROPOWR DEVELOPMENT

The cost of transportation and distribution to remote villages can be quite high, especially in densely forested areas and when coupled with low demand, which lends the argument that in Congo hydropower investments should be made in close proximity to demand. In general, it costs 50,000 USD/km for 33 kV lines, and distribution costs can be as much as USD 2,000 per connection.[14] For this reason, the development of SHP is most economically feasible at the local village level and if connected to mini-grids.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The change in precipitation patterns and resulting hydrological shift in the country affect the potential of SHP development, mainly due to the risk of low water levels and unpredictability. There are frequent floods in the Congo Basin (Mossaka) and low-lying areas of the country.[32] Decreased rainfall leading to aquifer deficit has affected Point-Noire, putting pressure on the city's water supply and disrupting the operation of hydropower plants in the Niari Valley.[32]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Large hydropower is predominant in Congo, and the general trend in governance following the energy sector reforms in 2018 is to open up the sector to private competition. The Government is actively seeking maximum exploitation of power capacity and potential, despite preliminary environmental and social feasibility studies recommendations, as demonstrated by the rejected IFC study.

The SHP sector in Congo is currently non-existent, although several small-scale plants are in the planning phase due to international development programmes and investment. Meanwhile, the domestic hydropower sector has continued to invest in large-scale hydropower projects and thermal electricity generation. Due to the distribution and connection costs, SHP development is best suited to local, village-level projects.

The main obstacles to the development of SHP in Congo include:

- Low rainfall in dry season due to climate change that will decrease hydropower production, leading to decreased stability;[3]
- Gaps in the legal, regulatory and institutional framework;
- Lack of local skilled workforce to design, install, operate and maintain SHP plants;
- Lack of tax exemptions on SHP equipment;
- Low electricity prices;
- Low awareness of SHP among the population;
- Expensive transmission costs through densely forested areas;
- The country's current financial situation minimizes the potential for future financing programmes.[29]

Despite these barriers, Congo has significant water resources for the development of SHP. The national electrification policy is keen to develop this potential to serve rural areas remote from the national electricity grid.

The main enablers for the development of SHP in Congo include:

- Available SHP potential;
- Increased rainfall and intensity in wet seasons due to climate change could increase hydropower production;
- Existing interest from international development institutions in SHP development in the country;
- Liberalized energy market with a relatively restrained regulatory landscape.[3]

Democratic Republic of the Congo

International Center on Small Hydro Power (ICSHP)

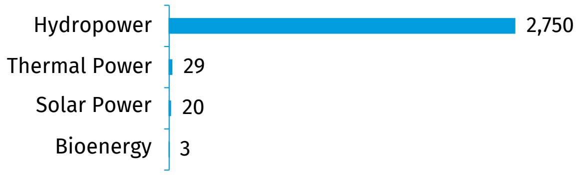
KEY FACTS

Population	89,561,404 (2020)[1]
Area	2,345,410 km^2 [2]
Topography	The Democratic Republic of the Congo (DRC) is a large and topographically diverse country with high plateaux, mountain ranges, a major valley, a large river basin and a low coastal plain. The Congo Basin, a large rolling plain at the centre of the country, has an average elevation of approximately 520 metres above sea level. The highest elevation in the country is at Margherita Peak, part of the Ruwenzori Mountain Range at the border with Uganda, with an estimated elevation of approximately 5,109 metres. This mountain range is part of the Western Rift Valley, which forms the country's eastern borders and includes the lakes Kivu, Edward, Albert, Mweru and Tanganyika. The active volcanic Virunga Mountains are also found in this area, at the border with Rwanda.[3]
Climate	The DRC has a largely equatorial climate with variations across the country's vast land area. The north and west of the country are hot and humid while the south, east and central areas are cooler and drier. The country's climate is driven by the seasonal migration of the Intertropical Convergence Zone across the equator. The mean annual temperature in the country is 24.4 °C. The northern and central to south-western areas average between 24 °C and 25 °C and the south and south-eastern savannah areas average between 22 °C and 23 °C. The tropical climate zones in the country experience a dry season (from April to October) and a rainy season (from November to March).[4,5]
Climate Change	Over the last 30 years, temperatures have been observed to increase by an average of 0.17 °C per decade. It is projected that the average temperature will increase by 1.7-4.5 °C and the average precipitation could increase by up to 8 per cent from the base period (1971–2000) by the end of the 21st century. Longer periods of dry seasons are also expected. However, no significant variations in rainfall patterns have been observed in the DRC.[5,6]
Rain Pattern	The DRC experiences a mean annual precipitation of 1,504 mm, with between 140 and 160 rainy days a year on average. In the central Congo Basin, precipitation averages between 1,800 mm and 2,200 mm a year. In the eastern regions, precipitation can reach 3,000 mm per year. In the coastal areas, the climate is drier and precipitation averages 810 mm a year.[6]
Hydrology	The DRC is home to over half of the African continent's surface water reserves and about one quarter of the continent's water resources, making it the most water-rich country in Africa. Approximately 30 per cent of the country's water resources originates from neighbouring countries. The Congo Basin covers approximately 98 per cent of the country, is the second largest in the world and hosts the world's deepest river, the Congo River. The other 2 per cent of the country is covered by the Nile Basin, which contributes approximately 20 per cent of the White Nile's flow. The DRC is also home to various rivers and lakes that it shares with its neighbouring countries, including the lakes Edward, Kivu, Albert and Tanganyika.[7]

ELECTRICITY SECTOR OVERVIEW

The main sources of electricity in the Democratic Republic of the Congo (DRC) are hydropower and thermal power, accounting for 99 per cent and 1 per cent, respectively, of total production, which amounted to 9,990 GWh in 2019. A further 0.1 per cent was from solar power. Production from hydropower, non-renewable thermal power and solar power amounted to 9,855 GWh, 107 GWh and 28 GWh, respectively, in 2019 (Figure 1).[8]

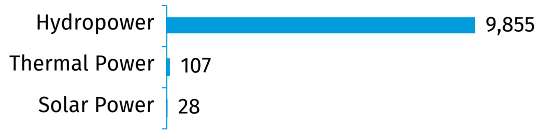
Figure 1. **Annual Electricity Generation by Source in the DRC in 2019 (GWh)**



Source: IRENA[8]

In 2020, the total installed capacity in the DRC was 2,802 MW with hydropower, non-renewable thermal power and solar power contributing 98 per cent, 1 per cent, 0.7 per cent and 0.3 per cent respectively. Installed hydropower capacity was approximately 2,750 MW, thermal power capacity was 29 MW, solar power capacity was 20 MW and bioenergy capacity was 3 MW in 2020 (Figure 2).[8]

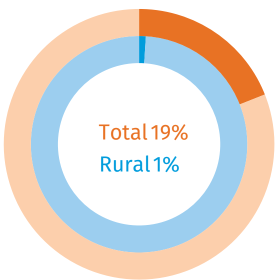
Figure 2. **Installed Electricity Capacity by Source in the DRC in 2020 (MW)**



Source: IRENA[8]

The electrification rate in the DRC was 19 per cent in 2020, with 49 per cent access in urban areas and 1 per cent in rural areas (Figure 3), making the DRC one of the countries with the lowest rates of electrification in the world.[9] There are significant issues of electricity shortage in the country, which make even customers connected to the national grid experience frequent blackouts. These issues are mainly caused by ageing and faulty equipment and lack of regular maintenance. Programmes for the rehabilitation of equipment were designed but have not succeeded in yielding considerable positive results yet mainly due to a gap in key skills and unrealistic objectives given the budgetary constraints.[10]

Figure 3. **Electrification Rate in the DRC in 2020 (%)**



Source: Energy Capital and Power[9]

The energy sector in the DRC is under the responsibility of the Ministry of Energy and Hydraulic Resources (MEHR), while the national utility responsible for the generation, transmission and distribution of electricity is the Société Nationale d'Électricité (SNEL). Due to the Government's promise to decentralize the electricity sector, private electricity operators have emerged, though remain regulated by SNEL. These include Virunga SARL, SOCODEE and BBOXX.[10]

Over the years, the electricity grid and transmission systems have been improved and enhanced. The high-voltage (HV) transmission system was 2,475.7 kilometres in 1970. This HV transmission system had extended to 5,260.7 kilometres by 1982, and by 2012 the distance serviced by the HV transmission network was 5,788 kilometres. In 2015, a second transmission system (400 kV) connecting Inga and Kinshasa and covering a distance of 277.3 kilometres was completed. This transmission network was financed by the European Investment Bank to reinforce and secure electricity generation for the city of Kinshasa. As of 2020, the total HV transmission system was 6,975.36 kilometres, including 1,774 kilometres of very HV direct current electric power transmission system extending from Inga in the west to Kolwezi in the south. There are several projects underway that aim to build transmission lines to neighbouring countries, including Uganda, Angola and Zambia. One of these projects is the proposed DRC–Angola Transmission Interconnector, which could link the two countries through a 250-kilometre 400 kV transmission line.[11,12,13,14]

There are several projects in various stages of completion to develop the energy sector in the DRC and increase access to electricity. These include the KivuWatt project, which has been partially completed and exploits the natural methane reserves of the Lake Kivu, shared with Rwanda, for electricity generation. There is also a concerted effort to accelerate the development of gas for domestic use, which could prove to be successful in providing value for the local community due to the country's vast resources in natural gas.[15,9]

The largest planned electricity project is the large-scale Grand Inga Dam Project, which, if completed, could single-handedly provide enough generation to meet 40 per cent of the continent's energy demand, making it the largest hydropower project in the world, with an estimated capacity of over 40,000 MW. One of the phases of the Grand Inga project, the Inga III dam, is currently underway and could provide 4.8 GW of capacity to the country. As the Inga III project advances, several other African countries have expressed interest in the project, with Eskom of South Africa and the Government of Angola signing agreements for the purchase of 2,500 MW and 5,000 MW of the project capacity, respectively.[9]

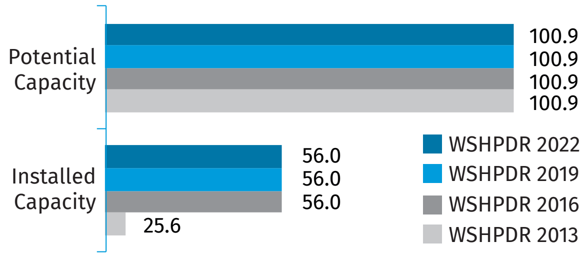
There are also projects that target other renewable energy sources such as the Kinshasa Solar City Project, which aims to build several solar power plants for a combined capacity of 1,000 MW. These energy projects contribute towards the country's goals of achieving universal electricity access by 2035 and reducing greenhouse gas emissions by 17 per cent by 2030.[9]

In the DRC, SNEL's tariffs are set by the Government and have not been revised since 2009 and are thus fixed at approximately 0.077 USD/KWh with variations based on inflation rather than changes in costs. Private operators fix their own tariffs in agreement with MEHR or relevant provincial authorities. Private operator Virunga SARL charges 0.21 USD/KWh (before taxes) in Goma and so does private operator SOCODEE for low-volume customers. For medium-volume customers, SOCODEE charges 0.16 USD/KWh. Private operator BBOXX charges between USD 17 and USD 100 per month for residential power service.[10]

SMALL HYDROPOWER SECTOR OVERVIEW

In the DRC, small hydropower (SHP) is defined as plants with an installed capacity of up to 10 MW. There was an estimated 56 MW of installed SHP capacity in 2017, which has not been updated as of the time of writing of this chapter. The total SHP potential identified has remained unchanged at approximately 101 MW since the previous edition of the *World Small Hydropower Development Report (WSHPDR 2019)* (Figure 4).[16]

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in the DRC (MW)**



Source: *WSHPDR 2019*,[16] *WSHPDR 2016*,[17] *WSHPDR 2013*[18]

There are five planned SHP projects in the DRC in Butembo, Kakobola, Beni, Lungudi and Masisi (Table 1) out of approximately 780 sites that were found to be suitable for SHP development.[14,9,20,21,22,23]

Table 1. **List of Selected Planned Small Hydropower Projects in the DRC**

Location	*Potential capacity (MW)*
Butembo	9.50
Kakobola	9.30
Beni	2.40
Lungudi	1.50
Masisi	0.22

Source: UNDP[19], AfDB[20], IJHD[21], Energy Capitol and Power[22], Hydro Review[23]

RENEWABLE ENERGY POLICY

The DRC does not have a comprehensive renewable energy policy framework. There is, as part of the National Strategic Development Plan 2019–2023 (NSDP), a highlighted need for the development of renewable energy sources, particularly the tremendous hydropower potential. This, however, is accompanied by an emphasis on the development and exploitation of natural gas.[24]

There are no specific government policies that target SHP development and no direct incentives for the development of SHP by the Government of the DRC. There are, however, donors and funding institutions interested in investing in the development of RE since the Government authorized a liberalization of the electricity sector. These include the World Bank, the African Development Bank (AfDB), the European Union and the United Kingdom Department for International Development (DFIF).[25]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

In the DRC, SHP plants are regulated by the same legislation as larger hydropower projects. The main legislation and regulation documents in the DRC concerning hydropower are:

- The 2014 Electricity Liberalization Law ref. 14/011;
- The Decree No. 18/054 of 2018 on the reduction of production and import/export costs of electricity;
- The Decree No. 18/053 of 2018 on setting the conditions for the import and export of energy to/from the DRC.[26]

COST OF SMALL HYDROPOWER DEVELOPMENT

In the DRC, the construction costs of SHP are site-specific. The main cost indicators are waterfall height and strength, with the cost falling as the height rises (Table 2). These costs are estimated based on previously built plants.[26]

Table 2. **Mean Costs of Small Hydropower Construction in the DRC**

Waterfall height	*Construction costs (USD/kW)*
High (> 200 m)	1,500–2,000
Medium (30–200 m)	2,000–4,000
Low (≤ 20 m)	4,000–6,000

Source: ANAPI[27]

BARRIERS AND ENABLERS TO SMALL HYDROPOWER DEVELOPMENT

The development of SHP in the DRC is mainly hampered by:

- Weakened institutional and regulatory framework: the decentralization law, the 2014 liberalization, the state disengagement law and the law on public utilities' transformation have not been effectively enforced due to lack of institutional support. This constitutes a discouraging factor for private parties interested in SHP;
- The centralized grid expansion in the country favours large and centralized generation assets to the detriment of smaller and localized generators such as SHP;
- High cost of initial capital and lack of affordable financial mechanisms discourage potential investors in the energy sector;
- Lack of institutional support for small-scale electricity projects;
- Lack of clear renewable energy policy in the country.

Enablers for SHP development in the DRC include:

- The 2014 liberalization law promises the decentralization of the electricity sector, thus inviting private actors and international investors to get involved in the sector. This would, if enforced, provide an enabling environment for the development of SHP;
- The abundant water resources in the country and the multiple identified potential sites for SHP.

Equatorial Guinea

Annabel Johnstone, Kaboni

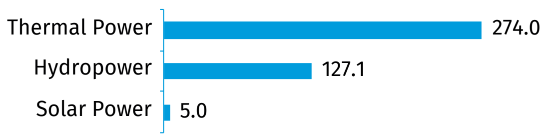
KEY FACTS

Population	1,432,744 (2021)[1]
Area	28,051 km^2[2]
Topography	Located in Middle Africa, Equatorial Guinea has a mainland region and an insular region. The latter comprises the islands of Bioko, which hosts the country's capital of Malabo, and Annobón in the Gulf of Guinea. The mainland of Equatorial Guinea begins on a narrow coastal plain, lined with mangrove swamps. From there, the land rises into an elevated plateau of thickly forested hills to the border with Gabon, reaching (in a few places) upwards of 1,219 metres above sea level. The highest point of Equatorial Guinea is Pico Basile at 3,008 metres and is located on the island of Bioko, which is dominated by three extinct volcanoes. The lowest point of the country is the costal border with the Atlantic Ocean (0 metres above sea level).[2]
Climate	The climate is tropical, hot and humid all year round with no specific rainy season, though rainfall is heaviest in October. The temperatures are higher from January to May (average of 27 °C in the city of Bata on the mainland and an average of 26 ° C in Malabo) and lower from July to September, when they drop to approximately 21 °C in the higher altitudes of the mainland, whereas Malabo experiences relatively constant temperatures all year round.[3]
Climate Change	Climate change projections for Equatorial Guinea encompass increased temperatures (average increase of 3-3.5 °C from a range of predictions under an average global temperature rise of 4.9 °C) and rainfall. Rainfall is projected to increase by a median of 40 mm in October-December, representing an increase of approximately 20 per cent.[4,5]
Rain Pattern	Mean annual precipitation is 2,205 mm, although rainfall patterns vary dramatically between the islands and mainland Equatorial Guinea. On the island of Bioko, precipitation is below 2,000 mm per year in Malabo, while it exceeds 3,000 mm per year in the rest of the island. The dry season on the island of Bioko runs from December to February, although it is more pronounced in the northern part, where Malabo is located; the rainiest period is from May to October. The slopes of Pico Basile experience high rainfall, with the location influenced by the prevailing wind. On the mainland, known as Rio Muni, there are two peak rainfall periods: from March to May and from September to November. The rains are also quite abundant from December to February, especially along the coast, and the only moderately dry period is from June to August.[3,4]
Hydrology	Aside from the sections of the Atlantic Ocean, the dominant water body is the Mbini River (known as the Woleu River in Gabon), which runs generally from east to west through central Rio Muni. To the north, the Campo River (called the Ntem in French-speaking Africa) marks part of the frontier with Cameroon. The Utamboni River flows through the south. To the south-west lies the Muni, which is an estuary of various rivers of Gabon and southern Equatorial Guinea. To the east, the de-facto border with Gabon follows the meandering course of the Kié (or Kyé) River, rather than the legal frontier.[6]

ELECTRICITY SECTOR OVERVIEW

Equatorial Guinea had an installed capacity of 406.1 MW in 2019, of which 127.1 MW came from hydropower, primarily from the Djibloho plant (120 MW) (Figure 1). This is set to more than double, once the 200 MW Sendje hydropower project is completed.[7,10] The completion date is unknown, but expected soon following a recent investment of EUR 122 million (USD 148 million) into the project. There is also a solar-powered micro-grid with a 5 MW plant installed in 2017 in Annobon.[8]

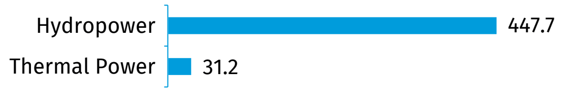
Figure 1. **Installed Electricity Capacity by Source in Equatorial Guinea in 2019 (MW)**



Source: Wise Power Systems,[8] African Energy Portal[9]

In 2019, the majority of the total electricity generation of 478.8 GWh was produced by hydropower (447.7 GWh), with the installed capacity of non-renewable sources (274 MW) only producing 31.2 GWh (Figure 2).[9] Final consumption was 598 GWh in 2019, excluding electricity imports, which are not documented. The amount of solar power generation from micro-grids is unknown.

Figure 2. **Annual Electricity Generation by Source in Equatorial Guinea in 2019 (GWh)**

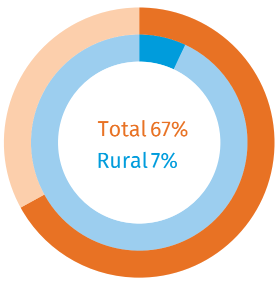


Source: African Energy Portal[9]

The state-owned electricity company Sociedad de Electricidad de Guinea Ecuatorial (SEGESA) under the Ministry of Mines and Hydrocarbons (MMIE) provides electricity under licensed monopoly and has several subsidiaries for generation, transmission and commercial operations. The SEGESA operates the country's two small electricity transmission networks, which comprise approximately 129 metres of high-voltage lines.[10] The network on the mainland serves the suburban area of Bata. The second distribution system, on Bioko, serves the capital Malabo and connects with the port of Luba. The electricity sector regulator is the Electricity Energy Regulatory Agency, while ownership of sectoral resources is left up to the national oil company GEPetrol. Equatorial Guinea is a member of the Central African Power Pool. Work on drilling three oil exploration wells in the Trident Energy-operated Block G oil production field commenced in 2021, and there are plans for the refurbishment and well intervention works across existing thermal plants.

In 2018, 67 per cent of the total population in the country had access to electricity: 90 per cent of urban residents and only 7 per cent of rural residents (Figure 3).[9]

Figure 3. **Electrification Rates in Equatorial Guinea in 2018 (%)**



Source: African Power Portal[9]

The Government of Equatorial Guinea is focusing on developing the fossil fuel industry within the country. In 2019, the Minister of Mines and Hydrocarbons (H.E Gabriel Mbaga Obiang Lima who is still in office at the time of writing) called for USD 1 billion of investment to develop 10 new fossil-based projects (of oil refineries and processing infrastructure). However, it is unclear whether suitable investment was raised for these projects.[12] The strategy to continue developing oil and gas resources in the country was repeated in discussions with the African Energy Chamber in 2020 as part of planning for recovery after the COVID-19 pandemic.[13]

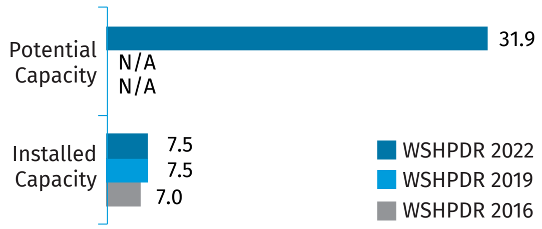
The Government of Equatorial Guinea has set electricity prices for enterprises and individuals in accordance with Law No. 3/2002. The electricity consumption price varies depending on the location and source of energy. Electricity consumers outside of Malabo and Bata are charged a fixed tariff per kWh. When the supplier is an independent producer, consumers are charged 0.099 USD/kWh. For independent diesel producers the price is 0.140 USD/kWh, while for independent hydropower producers the set price is 0.110 USD/kWh.[14]

SMALL HYDROPOWER SECTOR OVERVIEW

There is no official definition of small hydropower (SHP) in Equatorial Guinea. For this chapter, the definition of up to 10 MW will be used.

Although Equatorial Guinea is estimated to have 11–26 GW of hydropower potential, of which 50 per cent is deemed economically recoverable, SHP has received little attention in the country. Only three SHP plants were in use as of 2021.[11] In the south of Bioko, the old 3.8 MW hydropower plant in the town of Riaba has been operating at times at as low as 2 per cent of capacity due to lack of investment in maintenance and despite the increasing economic activity from the nearby freeport in Luba. The Riaba plant is to be refurbished and could see an increase in capacity to 6 MW, while the two micro-hydropower plants at Musola (0.4–0.5 MW) and Bikomo on the mainland (3.2 MW) are in need of upgrading.[11] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed SHP capacity remained unchanged (Figure 4). The reason for the change in potential capacity since *WSHPDR 2019* is due to access to a new geo-spatial study released in 2018.[18]

Figure 4. **Small Hydropower Capacities in the WSHPDR 2016/2019/2022 in Equatorial Guinea (MW)**



Source: *WSHPDR 2013*,[15] *WSHPDR 2016*,[16] *WSHPDR 2019*,[17] Korkovelos et al.[18]

The Bikomo plant on the mainland (3.2 MW) was recently rehabilitated, as announced in a 2019 project review report.[19] Following the success of the Riaba and Musola plants, there were hopes for support for a 10 MW plant at Ilachi on Bioko island, as mentioned in a United Nations Development Programme (UNDP) project document.[19] Although details are not publicly available, a pre-feasibility study for the Ilachi location as well as water resource evaluations at sites in Belebu and Bococo Drumenwas were underway in 2019.[20]

Table 1. **List of Operational Small Hydropower Plants in Equatorial Guinea**

Name	*Location*	*Capacity (MW)*	*Launch year*
Musola I and II	Bioko	0.5	1942
Riaba	Bioko	3.8	1986
Bikomo	Rio Muni	3.2	–

Source: UNEP[11]

A geo-spatial analysis study conducted on GIS mapping software in 2018 identified 30 potential micro-hydropower sites (0.1–1.0 MW) totalling 10.9 MW and six SHP sites (1.01–10 MW) totalling 13.5 MW. The findings of the analysis suggest that there is at least 24.4 MW of undeveloped SHP potential in Equatorial Guinea. The exact locations, names and individual details of the sites are unknown, but the results from the geo-spatial mapping are visible in the study report.[18]

A separate study by Électricité du France (EDF) has identified 10 potential sites on Bioko Island at the six main rivers of the Cónsul, Balaopi/Tiburones, Musola, Tudela/Moaba, Ilachi, Ruma/Grande and Bao, though the individual capacities were not stated. The same study found that the most promising site for SHP development would be the Ilachi River with a height difference of 200 metres and a combined capacity of 12 MW in the dry season (and up to 18 MW in the rainy season).[11] The exact locations or names of these sites are not listed either and it is not known whether there is an overlap with the sites identified in the 2018 geo-spatial study. For this reason, the potential capacity estimate provided in this chapter is subject to error and potentially underestimated, due to possible overlap of data sources and lack of transparency.

Another project exploring SHP opportunities in Equatorial Guinea was conducted through the UNDP. The project aimed to complete a hydropower demonstration programme on the island of Bioko and to support the ongoing refurbishment of existing facilities at Riaba and Musola.[21] The project had a target of installing one SHP plant and as of 2019 this had not yet been achieved due to project delays.[19]

RENEWABLE ENERGY POLICY

Energy policy decision making in Equatorial Guinea primarily focuses on oil and gas developments, while in the power sector the focus is predominantly on larger-scale generation, grid extension and transmission concerns. Two main laws responsible for the energy sector are the Fundamental Law of 2012 and the Hydrocarbons Law No. 8/2006. As for the electricity sector, Decree 20/2005 allows for the transformation of the electricity sector.[14] Electricity tariffs were set by Decree No. 03/2002 of 21 May 2002.

Apart from the electrification plan, which was unveiled by the President in 2011, there is no longer-term renewable energy or off-grid electrification section or separate plan. There is a lack of procurement and licensing processes for independent power producers (IPPs), which creates only limited scope for renewable energy technology entrepreneurship and for IPPs in general.[14] There is no specific legislation relating to SHP and estimates of cost of SHP specific to the country are unavailable.

The European Union is a potential financing partner through the ACP-EU Energy Facility. The strong business relations between China and Equatorial Guinea may lead to additional development finance. Additionally, Spain and France continue to provide some project assistance.[21] The UNDP project on SHP mentioned above has been financed through the Global Environment Fund.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Equatorial Guinea is vulnerable to climate shocks and rainfall variability from climate change and measures are being taken within the country to address the risks, however, most are focused on forest conservation and weather analysis, rather than transitioning the energy system towards renewable electricity generation. These commitments are outlined in the country's National Adaptation Plan of Action (NAPA), which is overseen by the Ministry of Fisheries and Environment. However, within this plan, there is little mention of the energy system. There is also no large-scale international financial programme to specifically support these ambitions.[22]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Given the Government priority to develop oil and gas resources, it is not likely that Equatorial Guinea will become a priority location for SHP relative to other Middle-African countries, though there is a good availability of hydropower resources near large anchor loads (Bioko Island). Any SHP project in Equatorial Guinea will be entering an immature market and developers should expect the barriers that come with this, alongside a lack of institutional motivation for SHP.

Barriers to the development of the sector include:

- No consideration of innovative financing mechanisms for renewable energy developments (e.g., feed-in tariffs, carbon finance), nor regulation considering SHP development strategy;
- High upfront costs (augmented by custom duties) remain a factor further increasing the cost of introduction of renewable sources in a small market (no economy of scale);
- Policy objectives largely focus on expanding the oil and gas sector;
- Subsidized petrochemical products do not reflect the actual cost of fuel-generated electricity, distorting renewable generation as expensive;
- Data quality issues pertaining to the exact locations of the potential SHP sites identified.

Enabling factors include:

- Promising studies of viable sites for exploitation, particularly near the capital city on the island of Bioko;
- Interest in SHP from development institutions, such as the UNDP.

Gabon

Annabel Johnstone, Kaboni

KEY FACTS

Population	2,172,579 (2019)[1]
Area	267,667 km^2 [2]
Topography	Gabon is divided into three distinct regions: a narrow coastal plain to the west, a hilly mountainous interior and a savanna in the far east and south. Rainforest covers nearly 85 per cent of the country's territory.[2] Significant mountains include the Cristal Mountains in the north-east and the central Chaillu Massif formed of granite, saddled by the Ogooué River, which carves through limestone. The highest peak in Gabon is Mount Bengoué, in the Crystal Mountains at an elevation of 1,070 metres. The highest peak in the Chaillu Mountains is Mount Milondo, at an elevation of 1,020 metres. The country also has hundreds of caves located in the dolomite and limestone rock formations in the central and eastern areas.[3]
Climate	Located on the Equator, Gabon has a hot and humid climate all year round in the north and in inland areas, with a short dry season from June to August. Average temperatures year-round range between 25 °C and 27 °C in coastal lowlands and between 22 °C and 25 °C inland. The country has experienced some of its highest temperatures along the coast and in the capital city of Libreville.[3]
Climate Change	Gabon has experienced a general warming trend with the mean annual temperature having increased by 0.6 °C since 1960. The number of hot days in the country is projected to increase by 25-75 per cent annually by 2060. Annual mean temperatures will increase by 1.8 °C by 2040-2059, according to the worst-case emissions scenario of up to 5.4 °C by 2100. Climate projections indicate that warming will occur across the country, with faster rates in the inland areas and slower rates in the coastal regions.[4,5]
Rain Pattern	Gabon receives an abundance of rainfall, typically ranging from 1,500 mm to 3,500 mm per year. The wet season lasts from October to May, with a mean monthly rainfall of 200–250 mm and peak average rainfall in October–November at 280 mm/month. However, mean annual rainfall in Gabon has dropped at an average rate of 3.8 mm monthly (approximately 2.6 per cent) per decade since 1960. The coastal areas of Gabon are expected to experience an increase in precipitation, while the inland areas may experience decreased precipitation. Country average precipitation is expected to experience a slight overall increase of 33.8 mm by 2040–2059, under a multi-model ensemble analysis of worst-case scenarios (RCP8). At the same time, rainfall variability is expected to increase with greater intensity and frequency of heavy rainfall.[4,5]
Hydrology	Gabon has substantial renewable water resources, with 166x10^9 m^3 per year, of which 98 per cent is produced internally and found as surface water (with a 36 per cent overlap with groundwater sources). The majority of the surface water is carried by the major river, the Ogooué (also spelt Ogowe), which is 1,200 km long and has several tributaries. Flowing through Gabon for almost its entire course, the river's drainage area extends for almost 222,700 km^2, within Gabon and also neighbouring Congo and Cameroon. The river originates in the north-east in Congo, and travels through the main watersheds of the Chaillu Massif and the Crystal Mountains, and empties into the Atlantic Ocean.[6,7]

ELECTRICITY SECTOR OVERVIEW

In 2019, Gabon had a total installed capacity of 632.3 MW, of which 334.3 MW came from renewable sources. The dominant renewable energy source in the mix is hydropower, accounting for 332.0 MW of installed capacity, with the remainder split between solar power (1.4 MW) and bioenergy (1.2 MW) (Figure 1).[8]

Net production plus imports of electricity in Gabon reached 2,331.5 GWh in 2018, compared to 2,327.1 GWh in 2017. In 2018, hydropower was the source of 980.9 GWh, a rise of over 7 per cent in just one year (913.6 GWh in 2017). Thermal generation stood at 839.8 GWh in 2018, down from 967.5 GWh in 2017.[10] Solar power and bioenergy generation were estimated at 2.1 GWh and 14.1 GWh, respectively, in 2018.[8] Thus, total electricity generation in the country in 2018 amounted to 1,836.9 GWh (Figure 2).[8,10] Gabon does not export electricity and is a net-importing country. Imports of electricity have been steadily increasing since 2013 and reached 445.6 GWh in 2019, demonstrating an increase of nearly 11 per cent compared to 2018.[8]

Figure 1. **Installed Electricity Capacity by Source in Gabon in 2019 (MW)**

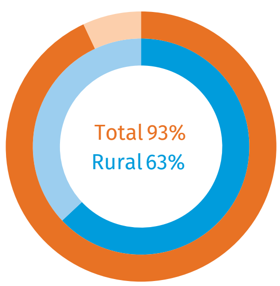
Note: This is an indicative estimate based on an average from several sources.

Figure 2. **Annual Electricity Generation by Source in Gabon in 2018 (GWh)**

Source: African Energy Portal,[8] SEEG[10]

Access to electricity across the population is at 93 per cent nationally, with 97 per cent in urban areas and 63 per cent in rural areas (Figure 3).[8] Increased household demand (15–20 per cent increase on a yearly basis in Libreville alone) is placing a strain on grid balancing. The Libreville grid — one of five isolated distribution areas in the country — is experiencing these pressures on the grid most strongly and load shedding still occurs in certain neighbourhoods. The lack of a national transmission grid has contributed to a tight supply-demand margin in a large number of the country's urban areas.[10]

Figure 3. **Electrification Rates in Gabon in 2018 (%)**



Source: Africa Energy Portal[8]

The Ministry of Mines, Petroleum and Hydrocarbons and the Ministry of Energy and Hydraulic Resources have joint responsibility for the energy sector. The Société d'Energie et d'Eau du Gabon (SEEG) is the sole generator, transmitter and distributor of electric energy in the country. SEEG is vertically integrated and holds a 20-year lease to the monopoly, which was renewed in 2017. Gabon is a member of the Central African Power Pool (CAPP).

The electricity sector is regulated by the Water and Energy Sector Regulatory Agency. The electricity tariff is capped at 0.23 USD/kWh for low-voltage single-phase power and declines to 0.09 USD/kWh based on usage (0.23 USD/kWh for 12 kW, 0.09 USD/kWh for 1 kW). For three-phase electricity, the tariff is calculated based on the time of use: for long use (over 2,880 hours), general use (1,441–2,880 hours) and short use (less than 1,441 hours) the tariffs are 0.13 USD/kWh, 0.15 USD/kWh and 0.16 USD/kWh, respectively.[11]

The electricity sector of Gabon and indeed its entire economy is currently heavily dependent on the large oil resources available within the country. Gabon is the fourth largest oil producer in Africa, and is considered to be in the top five richest African countries in terms of raw natural resources. The country has had plans to diversify the energy sector and remove oil dependence since 2010, as outlined in the Emerging Gabon Strategic Plan. The commitment to this objective was renewed in 2020 after the country was heavily affected by the oil price crash during the COVID-19 pandemic. With most of the population concentrated in the capital of Libreville and the rural population scattered in difficult to access areas, the current objectives are to enhance service to those connected, lower service prices and ensure access in rural communities.[12,13]

Since 2016 there have been four thermal plants in the country: two in Libreville, including a 128 MW plant in Owendo run by SEEG and a 70 MW plant in Alé nakiri run by the Social Democratic Party (SDP); and two in Port-Gentil, including a 48 MW plant operated by SEEG and a 52 MW plant run by the SDP, which is to be connected to the grid shortly. In addition to the SDP-owned 160 MW Grand Poubara hydropower plant that powers Franceville, Gabon has three major hydropower plants operated by SEEG. The Kinguélé plant has a capacity of 59 MW and is located roughly 200 km east of Libreville along the Mbei River, supplying Libreville via a 224 kV line. The second hydropower plant, Tchimbélé, is located along the same river and has a capacity of approximately 69 MW, while the third plant, Petit Poubara, near Franceville, has a capacity of 38 MW. The Grand Poubara and Alénakiri plants belonging to the SDP are operated under concession by China-based Sinohydro and Israel-based Telemenia.[14]

Several large hydropower projects are in development: the 85 MW Ngoulmendjim plant (550 GWh of annual generation) and the 15 MW Dibwangui plant (90 GWh) backed by the Gabonese Fund for Strategic Investments (FGIS) and Eranove; and the 35 MW Kinguélé-Aval plant (204 GWh) backed by FGIS and Meridiam. Furthermore, detailed preliminary studies of the Booué project on the Ogooué River (412 MW, 2,950 GWh) and the Tsengué-Lélédi project on the Ivindo River (300 MW, 1,286 GWh) have been initiated by the African Development Bank (AfDB) on behalf of the Economic Community of Central African States (EEECAS).[15] Gabon is examining financing options for two further hydropower projects: FE2 (36 MW, 240 GWh) and Empress Falls (88 MW, 500 GWh).[16]

In October 2019, French fund manager Meridiam signed a 33-year concession contract with the Government of Gabon to construct a 34 MW hydropower plant on the Mbei River, 100 km from Libreville. Construction was delayed due to the outbreak of COVID-19 and new projections state that the project will be completed in 2023.[17]

SMALL HYDROPOWER SECTOR OVERVIEW

There is no official definition of small hydropower (SHP) in Gabon. This chapter will use to the up to 10 MW definition of SHP. The hydropower sector in Gabon is heavily dominated by large-scale hydropower, and the country has significant hydropower potential of which an estimated 6,000 MW remains undeveloped.[18] Gabon has ambitions to become a net exporter of electricity in 2030, thus, the development of SHP to support internal electricity demand has viability.

There are three SHP plants in Gabon with a total installed capacity of 6 MW (Table 1).[19] There have not been any developments in the country's SHP sector since the publication of the *World Small Hydropower Development Report* (*WSHPDR) 2019*. However, SEEG launched a project worth USD 12.7 million for the rehabilitation of the Bongolo SHP plant, which operated at half (approximately 2.5 MW) of its installed capacity after 2010.[20] The change in installed SHP capacity since the *WSHPDR 2019* is a result of this rehabilitation work, and the change in potential capacity is due to access to new information from a geospatial feasibility study (Figure 4).

A geospatial assessment of SHP potential in Sub-Saharan Africa in 2018 found several opportunities to exploit mini- and small-scale hydropower in Gabon. The study found 105.9 MW of potential capacity at 343 sites with mini-hydropower potential (0.1–1 MW) and 412.1 MW of potential capacity available from 129 SHP sites (1–10 MW), resulting in a total of 518.1 MW of technical SHP potential. Though the locations and names of these sites are unknown, the mapped results from the geo-spatial analysis are visible in the study.[19]

RENEWABLE ENERGY POLICY

In July 2020, Gabon laid out its ambitions to become an emerging economy in the region by financing a rapid and sustainable transition from a "brown" to a "green" economy. The Strategic Plan for Gabon's Emergence (PGSE) is supported by a number of international organizations and coordinated by the joint Sustainable Development Goals (SDG) fund (alongside a commitment of USD 1 million) to accelerate a transition away from an extractive and oil-based economy to a green and sustainable one. The PGSE was born out of the commitment of Gabon to lower its greenhouse gas (GHG) emissions in 2017 and bolstered by the large economic shock of the oil-price crash in 2020, incentivizing the country's transition away from unsustainable markets. The planned transition will open up the market for SHP in the coming years and place renewable energy developers as valuable partners to the Government of Gabon. The joint project's approach aims to:

- Build an Integrated National Financing Framework (INFF) for both the PGSE, the SDGs and the transition to a green economy;
- Prepare the ground, through study and market assessment, for expanded use of innovative green financing mechanisms to power the country's sustainable development;
- Rationalize the development financing ecosystem in Gabon;
- Develop national capacities in the mastery of SDG financing instruments to accelerate the achievement of SDGs related to climate change at the global level; and
- Establish an effective and inclusive system for monitoring public resources allocated to the transition to a green economy, aiming at creating a nation-wide SDG financing dialogue mechanism.[25]

Hydropower plays an important role in this transition through the creation of jobs, capacity building and enabling mitigation of the nation's dependency on oil and gas as the primary energy sources. Thus, promotion of hydropower is seen as one of the four pillars of green transformation acceleration alongside the creation of green jobs, promotion of green entrepreneurship for youth and women and sustainable cities.[26]

In light of the recent PGSE, it is highly likely that the regulations regarding renewable power generation will change imminently to the benefit of both utility scale and SHP developers through simplified and accelerated licence pathways and an increase in financial mechanisms to advance investment. This is especially the case as the PGSE represents the first targeted, holistic policy development for renewable sources in Gabon.[16] As reported by the Director General of the Ministry of Energy and Hydraulic Resources, a key change in the licensing process for hydropower will be a move from the outdated least-cost, project-by-project approach to a licensing procedure inviting multiple stakeholders to perform exploitation of all available sites in a river basin — a system-scale approach.[27] It is important to note also that due to the joint SDG approach, environmental standards and ecosystem services are seen as highly valuable and so any prospective projects are likely to require a detailed Environmental and Social Impact Assessment (ESIA) and environmental risk mitigation reports.

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

The above mentioned PGSE should inject much needed innovation into finance mechanisms for SHP and general private investments in the hydropower sector of Gabon. Planned or existing projects may also be financed through national or international institutions. The AfDB-financed Fund for Development and Expansion and the European Fund (FODEX) provide financing to small and medium-sized companies.

The Overseas Private Investment Corporation (OPIC), a United States Government agency, offers project financing in Gabon. There is also scope for finance from Gabon Special Economic Zone (GSEZ), which was started in 2010 as a joint venture between Olam International Ltd., the Government of Gabon and Africa Finance Corporation with a mandate to develop infrastructure, enhance industrial competitiveness and build a business-friendly ecosystem in Gabon.[28]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Climate predictions see an increase in rainfall in Gabon in all scenarios, so it is likely that the country will have increased total discharge.[4] This would require special consideration of construction materials and design, as landslides would be more likely.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Though attention will undoubtedly be focused on large hydropower projects due to the large natural resource base of Gabon, there is considerable scope for SHP development, especially in rural energy access schemes where export scale evacuation lines are less viable due to primary forest. More information is needed on the regulation changes coming through with respect to licensing procedures based on catchment basins rather than site-by-site licensing. For SHP, it would be beneficial to partner with large hydropower developers, to exploit this regulation change efficiently. Overall, Gabon looks promising for SHP development, keeping the below barriers and enablers in mind.

The key barriers to SHP development include:

- Legal framework and regulations are likely to change imminently due to the development of the PGSE;
- Lack of local expertise;
- Inadequate energy, water and transportation infrastructure;
- High levels of bureaucracy;
- Poor quality of state services;
- Relatively high labour costs.[20,25,26]

The key enablers include:

- The strategic plan of Gabon to transition from a "brown" to "green" economy opens huge potential for hydropower development;
- The Doing Business score of Gabon (45) has been steadily improving, with considerable improvement in ease of setting up a business.[29]

Sao Tome and Principe

International Center on Small Hydropower (ICSHP)

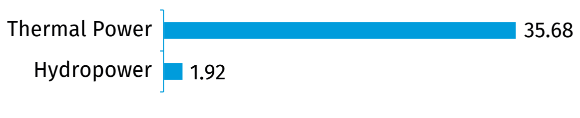
KEY FACTS

Population	219,161 (2020)[1]
Area	1,001 km^2[2]
Topography	Sao Tome and Principe is an archipelago consisting of two small islands and some islets located in the Gulf of Guinea, approximately 300 kilometres west of the African coast. The Islands are of volcanic origin and the terrains are predominately rugged with steep slopes, particularly in the western and southern regions on both islands. While volcanoes are present, neither island has experienced volcanic activity in recent centuries. The highest point is Pico de Sao Tome, at 2,024 metres, and is located in the western part of Sao Tome Island. The highest point on Pricipe Island is Pico de Principe at 948 metres, located in the southern region. Both islands have small coastal plain regions situated in the north-east.[2]
Climate	The islands have a tropical, maritime climate with little variation of temperature in a given region throughout the year. Temperatures in lower elevations and coastal regions are consistently in the upper 20s °C, while temperatures in higher elevations may drop to approximately 10 °C at night. Seasons are determined by rainfall with a dry season between June and August and a wet season between September and May.[2,3]
Climate Change	As islands, some of the most pressing concerns of climate change in Sao Tome and Principe are rising sea levels, coastal flooding and coastal erosion. These phenomena have been experienced already and are expected to intensify in the upcoming decades. Additionally, there have been noticeable elongated dry seasons, causing droughts, while prevalence of excessively heavy rainfalls and storms is increasing during the wet season, causing floods and landslides.[3]
Rain Pattern	Precipitation largely occurs during the wet season between September and May throughout the country, although average amounts vary by region, gradually decreasing from south-west to north-east. Average annual rainfall in the southern and western mountainous regions of both islands is above 5,000 mm and can exceed 7,000 mm in some areas. In the far north-eastern regions, annual rainfall is the lowest, approximately 760 mm.[2]
Hydrology	Within the mountainous terrain are many swift flowing rivers beginning in the country's interior highlands and flowing downwards to the coasts. The largest river is the Io Grande on Sao Tome draining in the south-east. Other important rivers on Sao Tome include the Abade, Manuel Jorge and Rio d'Ouro. The largest and most important river on Principe Island is Rio Papagaio. Many rivers have seasonal flows and weaken during the country's dry season.[4]

ELECTRICITY SECTOR OVERVIEW

In 2020, total installed capacity in Sao Tome and Principe was 38.6 MW, although total available capacity was considerably lower. On the country's grid, thermal power, largely diesel fuel, amounted to 35.68 MW (95 per cent) and hydropower to 1.92 MW (5 per cent) (Figure 1). Additionally, there were some other isolated systems in remote areas not connected to the grid amounting to approximately 1 MW. There are a total of 7 power plants in operation in the country, 6 of which are thermal power and 1 hydropower. None of the power plants operated with their full installed capacity in 2020, leaving a total available capacity of 22.15 MW (Table 1).[5]

Figure 1. **Installed Electricity Capacity by Source in Sao Tome and Principe in 2020 (MW)**



Source: EMAE[5]

Table 1. **Installed and Available Capacity in Sao Tome and Principe**

	Installed capacity (MW)	*Available capacity (MW)*
Sao Tome	34.80	20.31
Principe	2.80	1.24
Off-grid	1.04	0.60
Total	**38.64**	**22.15**

Source: EMAE[6]

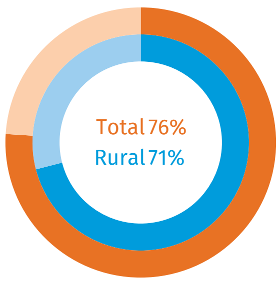
In 2020, total electricity generation was 109.6 GWh. Thermal power generated 104.7 GWh (95 per cent) and hydropower generated 4.9 GWh (5 per cent) (Figure 2). Net generation after energy used by power plants was 103 GWh. Due to significant inefficiencies, the electricity sector has experienced large annual losses in recent years and in 2020, losses represented 33.1 GWh, or over 32 per cent. After losses, the actual total electricity consumed in the country was 69.9 GWh for the year.[5]

Figure 2. **Annual Electricity Generation by Source in Sao Tome and Principe in 2020 (GWh)**

Source: EMAE[5]

The overall electrification rate in 2020 was 76 per cent, including over 78 per cent in urban areas and 71 per cent in rural areas.[6] Most of the electricity consumption in the country is concentrated in the capital city and surrounding areas. In 2020, there were 50,402 electricity customers that consumed a total of 69.9 GWh. The 42,489 residential customers represented 84 per cent of total customers and consumed 49 per cent of the electricity. Government and state institutions consumed 16 per cent of the total, commercial customers 13 per cent, industrial customers 8 per cent and the remaining 14 per cent was distributed amongst other types of customers.[5]

Figure 3. **Electrification rate in Sao Tome and Principe in 2020 (%)**



Source: World Bank[6]

In 2014 the electricity sector was restructured under Legal Framework of the Electricity Sector (RJSE) Decree-Law No. 26/2014. This decree essentially liberalized the market for private entities to invest in electricity production, however, there is a lack of clear regulation. As of 2020, the Government was working with external partners such as the United Nations Development Programme (UNDP) to create complimentary legislation that would further outline the standards for a liberalized market. Currently, the main electricity company is the Water and Electricity Company (EMAE), which is 51 per cent owned by the state and 49 per cent owned by private companies. EMAE is responsible for all the electricity production, distribution and transmission in the country. The distribution and transmission networks use a combination of underground and overhead medium- and low-voltage lines from 0.4 kV to 30 kV.[7]

With the support of international donors, the Government has made efforts to improve and extend the transmission and distribution network, construct new substations, transformation posts and a new national dispatch centre based on smart technologies and train technicians in order to adapt to the new quantitative and qualitative technological requirements of the public electricity service. In 2016 and 2017, transmission and distribution lines were rehabilitated and extended to the north and north-east to Santa Catarina Island and to the south of the island of Sao Tome as far as Sao Joao dos Angolares, as well as to Monta Alegre and Praia Burra in the island of Principe.[8]

Expansion of electricity access and reliability is incorporated into many of the recent national plans. The Sao Tome and Principe 2030 Transformation Agenda set out the Government's goals to pursue sustainable development, provide access to energy as an essential public good to the entire population, preserve the environment by designing projects that minimize negative environmental impacts and creating favourable conditions for the implementation of relevant environmentally friendly solutions and promote public-private partnerships with companies that have financial capital, technologies and human resources in the field of renewable energy.[7] The National Development Plan of 2017–2021 also highlighted the need to extend electricity access to the whole population as well as the need to rehabilitate the distribution and transmission infrastructure to avoid losses and increase energy efficiency, to increase electricity production through encouraging public-private partnerships and investments and to ensure a 50 per cent share of renewable energy sources on the grid by 2030. Additionally, the World Bank provided support to the Ministry of Infrastructure and Natural Resources with the preparation of a Least Cost Development Plan in 2018, which set out a roadmap to attain the necessary new generation capacities with the lowest cost investments.[7]

Electricity tariffs are set by EMAE and are approved by the General Regulatory Authority (AGER). Tariffs vary depending on the category and volume of consumption and are not differentiated by region due to the uneven distribution of the population across the country (Table 2).

Table 2. **Electricity Tariffs in Sao Tome and Principe**

Type of consumer	*Tariffs (STD/kWh (USD/kWh))*
Domestic:	
< 100 kWh	1.67 (0.07)
100–300 kWh	2.45 (0.11)
> 300 kWh	3.84 (0.17)
Commercial	3.84 (0.17)
Government, state institutions	6.03 (0.26)
Embassies, international institutions, other	7.03 (0.30)

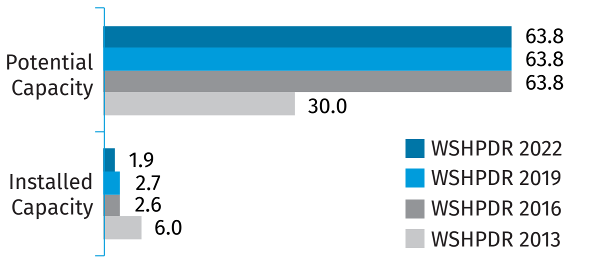
Source: EMAE[8]

SMALL HYDROPOWER SECTOR OVERVIEW

Small hydropower (SHP) is defined as power plants up to 10 MW, with a further breakdown into mini-hydropower (101 kW–1 MW) and micro-hydropower (1–100 kW). For the purposes of this chapter, all hydropower plants up to 10 MW will be considered SHP.

In 2020, the installed capacity of SHP in Sao Tome and Principe was 1.92 MW.[5] According to a study carried out in 2008 by CECI Engineering Consultants, Inc., there is a total potential capacity of 63.8 MW, indicating that just 3 per cent of the potential capacity is currently in operation.[7] Compared to the results of the *World Small Hydropower Development Report (WSHPDR) 2019*, potential capacity has remained the same and installed capacity has decreased due to removing plants not in operation for several years from the value of installed capacity (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Sao Tome and Principe (MW)**



Source: EMAE,[5] ALER,[7] *WSHPDR 2019*,[9] *WSHPDR 2016*,[10] *WSHPDR 2013*[11]

Historically, there have been four SHP plants in the country, although only one has been in operation in the past decade. The Contador plant, located in the north-western region on Sao Tome Island, has been in operation for over 50 years and is in need of refurbishment. The installed capacity is 1.92 MW but the current available capacity is approximately 1.8 MW. As of 2020, a rehabilitation project on the Contador plant has been approved with financial support of the World Bank with aims to increase the installed capacity to up to 4 MW. The budget for this project will be USD 39 million.[7]

The three old SHP plants that are now no longer in use are the Guégué, Agostinho Neto and Papagaio. The Guégué was constructed in 1941 with a capacity of 320 kW and closed in 2011. While some infrastructure is still at the site, the turbine and electrical system have been fully removed. In 2019, private company STP Urbano made an agreement to rebuild an SHP plant at that location. The company plans to demolish most of the remaining infrastructure and build a plant with a capacity of 1 MW. The commencement on construction of this project has not yet been announced.

The Agostinho Neto plant was constructed during colonial times and later modernized with a capacity of 344 kW. Due to electromechanical problems, the plant was dismantled in 2007 and has been inoperable since. STP Urbano has also shown interest in demolishing and rebuilding the plant, but no concrete purchase has been made. The Papagaio plant was the only hydropower plant to exist on Principe Island. It was constructed in 1993, first with an oversize 400 kW turbine but after two weeks changed for an 80 kW turbine that was in operation for just a few weeks before the transformer was brought to be installed at a nearby thermal power plant instead. In June 2020, a call for proposals to carry out a feasibility study on the project was launched, with no further updates since.[7]

The 2008 study of SHP potential in Sao Tome and Principe identified 34 sites with a combined potential capacity of 63 MW and estimated annual production of 244 GWh (Table 3).[7] The large majority of the sites are located on Sao Tome Island, while three of them are on Principe Island. Development of these sites would more than double total installed capacity and electricity generation for the country, as well as provide access to electricity in nearby remote communities.

Table 3. **List of Selected Potential Small Hydropower Projects in Sao Tome and Principe**

Name	*Location*	*Potential capacity (MW)*
Dona Eugénia	Io Grande River	9.6
Monte Rosa	Quija River	3.75
Bombaim	Abade River	3.5
Santa Irene	Lemba River	3.0
Claudino Faro	Abade River	2.0
Mato Cana	Abade River	2.0
Neves	Provoz River	2.0
Santa Luzia	Manuel Jorge River	1.15
S. João	Cantador River	0.9
Santa Clara	Manuel Jorge River	0.89
Cruz Grande	Do Ouro River	0.88
Monte Verde	Xufexufe River	0.80
Mateus Sampaio	Umbugu River	0.50
Almeirim	Agua Grande River	0.44

RENEWABLE ENERGY POLICY

Policy development, expansion and improvement of the energy sector, customer services and public services delivery all fall within the Government's priorities. The Government has mobilized resources to restructure the energy sector in order to create a more attractive investment environment, particularly for private investment in renewable energy infrastructure. Ongoing programmes, carried out with the support of development partners, are the main line of action. At present, no incentives or financial mechanisms exist to support the development of renewable energy sources, including SHP. However, regulations on renewable energy and SHP plants specifically are being drafted with the support of national and international consultancies.[9]

The National Development Plan 2017–2021 set targets for renewable energy including a 30 per cent share in electricity generation by 2021 and a 50 per cent share by 2030. In 2020, renewable energy share in electricity generation was 5 per cent, indicating that the 2021 target will most likely be missed. The renewable energy sources prioritized by the country are hydropower, solar power and biomass. There is not much potential for wind power on the islands due to the steep slopes of its terrain. There have been 34 potential sites identified for approximately 63 MW of hydropower, 25 sites for solar power for over 62 MW and one site for biomass identified for 12.5 MW.[7]

In 2019, the Global Environment Facility (GEF) and the United National Industrial Development Organization (UNIDO) approved a USD 24.93 million grant, of which USD 1.58 million would come directly from GEF and the rest would come from co-financing. This grant, named the Promotion of Investments in Renewable Energy and Energy Efficiency in the Electricity Sector, has multiple aims focusing on technical assistance and training. Activities in the scope of this grant include UNIDO working directly with the Government of Sao Tome and Principe to create clear renewable energy policies and create any legislation required to achieve them, as well as preparing a National Sustainable Energy Investment Plan to present to potential investors in at least two investment forums.[7]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

With the support of the UNDP, the Promotion of Sustainable Development and Hydroelectric Production Interconnected or in an Isolated Grid, more commonly known as The Energy Project, was created in 2017. It secured USD 20.7 million from multilateral and private sources to help establish the required institutional and legal framework for hydropower investment and development in the country.[12] A set of activities is underway with the objective of removing both technical and institutional barriers, including:

- Organizational restructuring of the Department of Natural Resources and Energy;
- Creation of support mechanisms and incentives for independent producers of electricity from renewable sources;
- Development and implementation of the Water Law;
- Development of the National Forest Development Plan;
- Update of the Forest Law.

Development of regulations for the electricity sector include:

- Regulation of energy generation from different sources of renewable energy (hydropower, solar photovoltaics, biomass and wind power);
- Sanctioning regime applied to electric power producers;
- Regulation of connection of new producers to the grid.

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

The Government of Sao Tome and Principe has worked with several international banks, donors and organizations to secure funding for SHP. In 2018, the African Development Bank through its Sustainable Energy Fund for Africa approved a USD 1 million grant for the development of mini-hydropower in Sao Tome and Principe. The grant is to provide the necessary funding for feasibility studies and environmental impact assessments at potential SHP sites. The aim is that the information gathered by these studies will attract investors in the sector. The initial locations that these studies will take place are at the Monte Rosa, Monte Verde and Santa Irene potential project sites.[7,13]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The country's hydropower sector has significant potential for development, as shown in the studies carried out. Therefore, boosting development will require raising private funds, taking into account the legal instruments that are being developed to increase the share of hydropower in the national energy mix and minimize the country's environmental impact.

The major barriers to SHP development in Sao Tome and Principe include:

- Institutional constraints due to the lack of a national strategy for hydropower and other renewable energy sources;
- Lack of an Electricity Master Plan;
- Lack of legislation and adequate implementation of the recommendations of the 2008 study by CECI Engineering Consultants, Inc.

The major enablers for SHP development in Sao Tome and Principe include:

- Most of the SHP potential is untapped and many sites have already been identified with their respective capacities;

- Access to electricity in the country is not universal, particularly in rural or remote areas. SHP development in remote areas can bring electricity to communities that have been without;
- Currently, fossil fuels account for 95 per cent of electricity generation. SHP could be vital to achieve the goal of 50 per cent renewable energy by 2030.

1.3. Northern Africa

Countries: Algeria, Egypt, Morocco, Sudan, Tunisia

INTRODUCTION TO THE REGION

The electricity sectors of countries in the Northern Africa region are characterized by the dominance of state-owned companies and, with the exception of Sudan, heavy reliance on fossil fuels. In Algeria, two public companies dominate the energy market, with one focusing on hydrocarbon production and trade and the other managing electricity production and distribution as well as gas distribution. Almost all of the country's electricity is generated from natural gas, combined cycle and steam power plants. The electricity sector of Egypt is divided between 16 state-owned companies operating under the umbrella of the Egyptian Electricity Holding Company. Thermal power plays the dominant role in electricity generation in the country, although a significant share of installed capacity and generation is accounted for by renewable energy sources. In Morocco, the electricity sector is dominated by the state-owned National Office of Electricity and Potable Water, which acts as the sole buyer of electricity and also operates some of the largest plants in the country. The primary sources for electricity generation in Morocco are coal and natural gas, while renewable energy sources serve in a supplementary role. In Sudan, the electricity sector is controlled by five companies under the Ministry of Energy and Petroleum. Hydropower and thermal power are both major sources of electricity generation in Sudan and are employed in a complementary capacity. Tunisia operates a partially liberalized electricity market. While the main actor in the country's electricity sector remains a state-owned company, smaller private companies also have a significant presence. Tunisia is heavily dependent on fossil fuels for electricity generation, with thermal power accounting for over 97 per cent of electricity generation in 2019.

The leading hydropower producer in the Northern Africa region is Sudan, where hydropower accounts for the largest share of generated electricity, although the installed capacity of thermal power slightly exceeds that of hydropower. In Egypt and Morocco, hydropower plays an important supplementary role in electricity generation. Egypt and Sudan share the Nile River as their primary source of both hydropower and irrigation, resulting in a complex but generally amicable shared water use relationship between the two countries. Tunisia and Algeria have some hydropower capacity, but its share of the electricity supply of both countries is relatively minor.

An overview of the electricity sectors of the countries in the Northern Africa region is provided in Table 1.

Table 1. **Overview of Northern Africa**

Country	*Total population (million people)*	*Electricity access, total (%)*	*Electricity access, rural (%)*	*Total installed capacity (MW)*	*Electricity generation (GWh/year)*	*Hydropower installed capacity (MW)*	*Hydropower generation (GWh/year)*
Algeria	43	100	100	21,999	87,034	228	152
Egypt	106	100	100	59,530	197,357	2,832	15,038
Morocco	36	100	100	10,677	40,348	1,770	1,654
Sudan	44	55	41	4,137	16,846	1,907	10,210
Tunisia	12	100	100	5,653	20,217	62	66

Note: Data in the table are based on data contained in individual country chapters of the *WSHPDR 2022*; years may vary.

REGIONAL SMALL HYDROPOWER OVERVIEW

The definition of small hydropower (SHP) in Northern Africa varies by country. Algeria and Morocco adhere to the up to 10 MW definition of SHP, with additional subcategories for hydropower plants within the 0–10 MW range. By contrast, Sudan has adopted the up to 5 MW definition of SHP. There is no official definition of SHP in Egypt or Tunisia.

A comparison of installed and potential SHP capacities in the region is provided in Table 2.

Table 2. **Small Hydropower Capacities by Country in Northern Africa (MW)**

Country	*Local SHP definition*	*Installed capacity (local def.)*	*Potential capacity (local def.)*	*Installed capacity (≤10 MW)*	*Potential capacity (≤10 MW)*
Algeria	Up to 10 MW	47.1	47.1*	47.1	47.1*
Egypt	N/A	N/A	N/A	0.0	120.0
Morocco	Up to 10 MW	30.5	300.0	30.5	300.0
Sudan	Up to 5 MW	N/A	N/A	7.2	2,228.6
Tunisia	N/A	N/A	N/A	17.0	56.0
Total	**-**	**-**	**-**	**101.8**	**2,751.7**

Source: *WSHPDR 2022*[1]

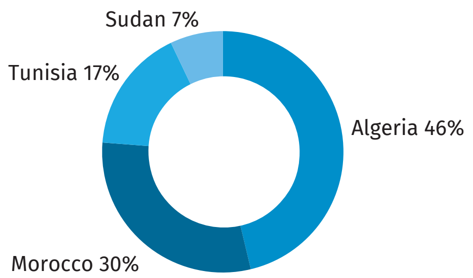
Note: *Based on installed capacity.

The installed capacity of SHP up to 10 MW in Northern Africa is 101.8 MW, while potential capacity is estimated at 2,751.7 MW. Relative to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed capacity decreased by approximately 9 per cent due to more accurate data on the operational status and installed capacities of existing SHP plants in Egypt and Morocco. The estimate of potential capacity for SHP up to 10 MW in the region increased five-fold due to a reassessment of the SHP potential of Sudan and Egypt.

While large hydropower plays an important role in electricity production in Northern Africa, the SHP sector in the region is very small by comparison, accounting for approximately 1 per cent of the total installed hydropower capacity. Little SHP development has taken place in the region over the last decade, with the installed SHP capacities of Egypt, Morocco, Sudan and Tunisia either remaining constant or declining due to the decommissioning of existing plants. The installed SHP capacity of Algeria has increased relative to the *WSHPDR 2019* as a consequence of the inclusion of a previously existing plant in the country's SHP total rather than any new developments in the last few years. SHP development in Northern Africa is hindered by a number of factors common to many countries in the region, including the availability of cheap fossil fuels, lower profitability of SHP relative to solar power and wind power plants and limited water resources in many parts of the region, as well as a lack of detailed data on potential SHP sites.

The national share of regional installed SHP capacity up to 10 MW by country is displayed in Figure 1, while the share of total national SHP potential utilized by the countries in the region is displayed in Figure 2.

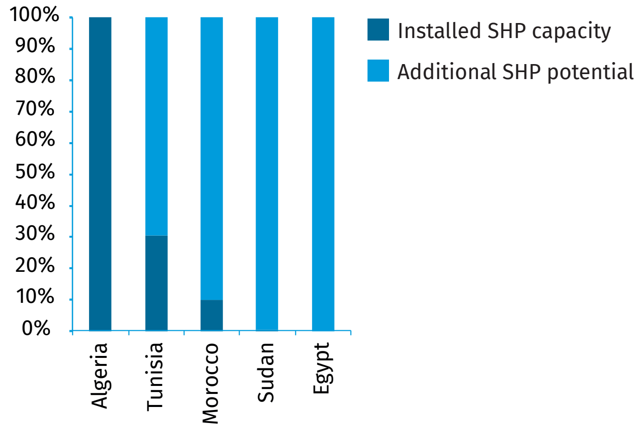
Figure 1. **Share of Regional Installed Capacity of Small Hydropower up to 10 MW by Country in Northern Africa (%)**



Source: *WSHPDR 2022*[1]

Note: Egypt not included due to absence of SHP plants up to 10 MW.

Figure 2. **Utilized Small Hydropower Potential up to 10 MW by Country in Northern Africa (%)**



Source: *WSHPDR 2022*[1]

In **Algeria**, the total installed capacity for SHP up to 10 MW is 47.1 MW. As there are no reliable estimates of the country's potential capacity, it is currently assumed that all SHP potential in Algeria is fully utilized. The installed capacity of Algeria increased relative to that reported in the *WSHPDR 2019* due to the inclusion of the previously unreported Ighzerouftis SHP plant in the country's SHP total. However, no SHP development has taken place in the country in recent years. Furthermore, the Government of Algeria has indicated its intention to phase out hydropower in order to redirect available water for irrigation and drinking water supply, and hydropower development has been entirely excluded from the country's New National Programme for Renewable Energy Development 2015–2030.

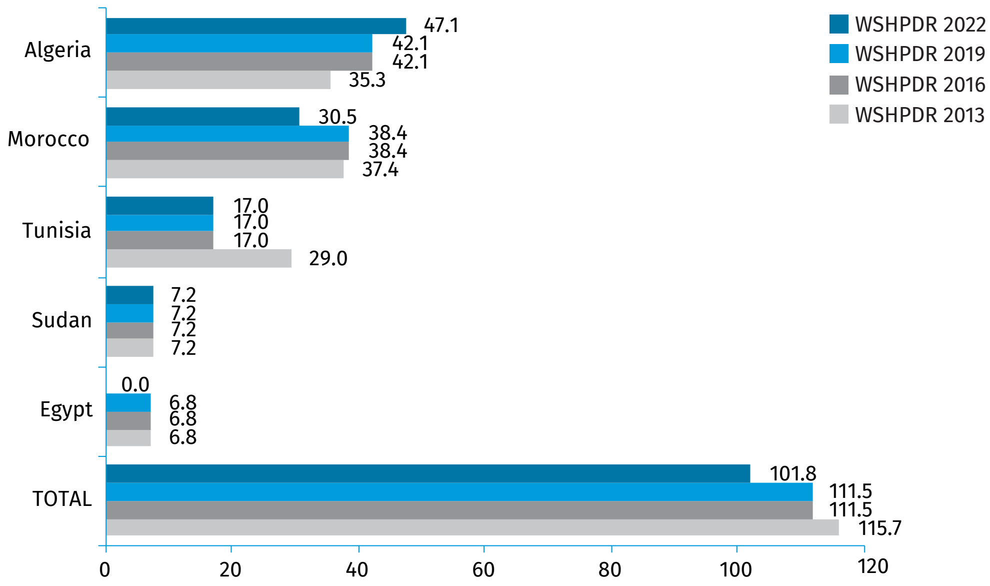
There were no operational SHP plants up to 10 MW in **Egypt** as of 2021, although several plants were in operation in the country in previous years. The potential capacity of SHP up to 10 MW has been recently revised from 51.7 MW to 120 MW. The country plans to develop several SHP sites with capacities ranging between 2 MW and 5 MW, although the project has not yet been confirmed due to concerns over its environmental and social impact.

Morocco has 30.5 MW of installed capacity for SHP up to 10 MW, while the potential capacity is estimated at approximately 300 MW, indicating that approximately 10 per cent of the SHP potential has been developed. As part of the Government's strategy to promote renewable energy sources by 2030, a number of hydropower projects have been approved for development by the private sector, of which 11 projects with a total capacity of 61.5 MW are under construction.

In **Sudan**, the installed capacity of SHP up to 10 MW is 7.2 MW, while the latest estimates put the country's SHP potential at 2,228.6 MW, indicating that less than 1 per cent has been developed. Although Sudan does not have an integrated renewable energy policy document, the country has been making efforts to develop its renewable energy potential and aims to reach at least a 50 per cent share of total electricity generation produced by renewable energy sources by 2031.

The total installed capacity for SHP up to 10 MW in **Tunisia** is 17 MW, while the estimated potential capacity stands at 56 MW, indicating that 30 per cent of the known potential has been developed. There has been no change in either installed SHP capacity or estimated potential capacity of the country since the *WSHPDR 2019*. The renewable energy strategy in Tunisia is focused primarily on solar and wind power. By contrast, the development of SHP has received relatively little interest in recent years, although in 2019 the National Company for the Exploitation and Distribution of Water of Tunisia invited bids for the construction of two micro-hydropower plants. The status of these two projects is currently unknown.

Figure 3. **Change in Installed Capacity of Small Hydropower up to 10 MW from *WSHPDR 2013* to *WSHPDR 2022* by Country in Northern Africa (MW)**



Source: *WSHPDR 2022*,[1] *WSHPDR 2013*,[2] *WSHPDR 2016*,[3] *WSHPDR 2019*[4]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The key barrier to SHP development in **Algeria** is weak support for renewable energy technologies and a trend away from hydropower development in particular. Additional barriers include limited financial resources and the low cost of generation from fossil fuels. In light of the Government's decision to not only halt the future development of hydropower but to additionally phase out existing hydropower capacities due to water scarcity, there is little prospect for SHP development in the country.

Barriers to SHP development in **Egypt** include competition from other renewable energy sources, lack of Government interest in SHP and inadequate data on available SHP potential. However, as the Government's policies on renewable energy sources have been formulated fairly recently, the possibility exists that the utility of SHP for diversifying the country's energy mix may be reconsidered in the future. In addition, the country's substantial undeveloped SHP potential, including the large number of irrigation canals and other hydraulic infrastructure, presents many opportunities for SHP development in certain parts of the country.

While **Morocco** has made considerable progress in diversifying its energy mix, SHP development in the country faces stiff competition from wind power and solar power, with returns on investment from SHP projects being less attractive than those from other renewable energy sources. Lack of public interest in SHP and of focused research in the field, as well as concerns over the country's limited freshwater resources, pose additional obstacles for SHP development. Nonetheless, the availability of data on potential SHP sites could serve as the basis for future interest in SHP development in the country.

The development of SHP projects in **Sudan** is hampered mainly by the lack of a comprehensive renewable energy policy, the Government's focus on large hydropower at the expense of SHP, irregular rainfall and low expected returns on investment. At the same time, Sudan possesses the greatest known undeveloped potential in the region for SHP up to 10 MW and emerging renewable energy policies may favour SHP development in light of the country's ambitious renewable energy targets to 2030.

Key barriers to SHP development in **Tunisia** include limited technical capacities and limited specialization to undertake feasibility studies, competition with conventional and renewable energy sources and a lack of stable funding for SHP. At the same time, Tunisia has experienced a marked increase in rainfall in recent years, leading to dramatic increases in annual hydropower generation from existing capacities. If this trend continues, it could make hydropower and SHP in particular a more promising source of renewable energy in the country.

Algeria

Amine Boudghene Stambouli, University of Sciences and Technology of Oran; and International Center on Small Hydro Power (ICSHP)

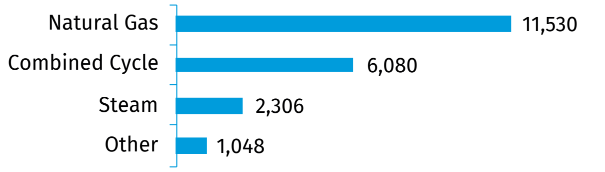
KEY FACTS

Population	43,424,000 (2019)[1]
Area	2,381,741 km² [2]
Topography	Algeria is made up of four main topographic zones. To the north, along the Mediterranean coast (1,200 km), stretches the narrow Tell plain, varying in width from 80 km to 190 km. The Tell Plain and the adjoining valleys are home to most of the country's agricultural land. On the borders of the Tell, two mountain ranges are oriented from east to west: the Tell Atlas to the north and the Saharan Atlas to the south, which merge towards the east of Algeria, forming the Aures massif. South of the Saharan Atlas stretches the Sahara Desert, representing 80 per cent of the surface area of Algeria. South of the Sahara stretches a succession of desert highlands, the Hoggar massif, where the highest peak in Algeria, Mount Tahat at 3,003 metres, is located. Approximately half of the territory of Algeria lies at 900 metres or more above sea level and approximately 70 per cent of the area is between 760 and 1,680 metres in elevation.[2,3]
Climate	The north of Algeria is in the temperate zone and its climate is like that of other Mediterranean countries, although the diversity of the relief creates strong temperature contrasts. The coastal region has average winter temperatures of 10-12 °C and average summer temperatures of 24-26 °C. Further inland, winter temperatures average 4-6 °C, with frost and occasional snow on the massifs; summer temperatures average 26-28 °C. In the Sahara Desert, temperatures range from 10 °C to 34 °C, with extreme peaks of 49 °C.[4]
Climate Change	Climate experts estimate that due to global warming, temperatures in Algeria will rise by 4-4.5 °C by 2050. As a result of the increased frequency of torrential rains, in 2009 the highlands of Ghardaïa and Bechar experienced flooding for the first time, and in the south of the country, in 2020 daily rainfall exceeded the normal annual average. Other observed consequences of climate change include high sea levels and destructive waves, causing erosion and even disappearance of beaches to the west of Algiers, demographic pressure, reduction in water run-offs, scarcity of water resources, degradation of hydraulic infrastructure and threat to wetlands.[5]
Rain Pattern	Precipitation patterns in the country can be separated into four key regions. The first region is located to the east in the high plains, and includes the Sersou plateau (Ain-Oussera region, Ksar el Boughari), while to the west it includes the region of Ras el Ma. These territories lie in relatively high altitudes (580–1,194 metres), are sheltered and characterized by low and irregular rainfall with averages of less than 400 mm per year. The second region, located in the west and the centre of the country, is characterized by a position of relative shelter from the rain flows from the west and north-west and low relief. The annual precipitation averages are below 500 mm and are slightly less irregular than in the first region. The third region, encompassing mountainous areas as well as the high interior plains, receives irregular rainfall, with the annual average ranging from 500 mm to just over 800 mm. The fourth region is located in the east of the Tell Atlas and experiences irregular precipitation with maximum rainfall in the cold autumn and winter and minimum in summer, with annual averages ranging from 488 mm to 854 mm.[6,7]
Hydrology	The estimated amount of renewable water resources in Algeria is approximately 19 billion cubic metres per year and approximately 450 cubic metres (m³) per capita per year. This is below the recommended 500 m³ per capita per year scarcity threshold, indicating a water crisis in the country. Furthermore, water resources are characterized by high variability. The rivers in Algeria are numerous, but the majority of them have short courses. They mostly rise in the mountains near the coast and flow with great force through deep and rocky channels, presenting the characteristic mountain torrents. The Chelif River, the longest and most important river of Algeria, runs between the Atlas Mountains and Mediterranean Sea, is 725 km long and has an irregular flow, with the longest continuous flow being from November to March. The Djedi River is 479.6 km in length, making it the second longest river in Algeria. Similar to the Chelif, it begins in the Saharan Atlas Mountains at an elevation of 1,402 metres. The Djedi empties into Lake Chott Melrhir, which is located at 3.6 metres below sea level, the lowest point in Algeria.[6,7,8,9]

ELECTRICITY SECTOR OVERVIEW

Total electricity generation in Algeria was 87,034 GWh in 2019 (Figure 1).[10] Of this, 81,526 GWh came from state-owned power plants and independent power producers, while 5,508 GWh came from autonomous production.[10] More than 99 per cent of energy production and consumption, including in the electricity sector, is derived from natural gas and produced from 33 stations located in the southern region of the country.[11] Electricity production growth has been two times slower since 2015 and is almost entirely from gas.

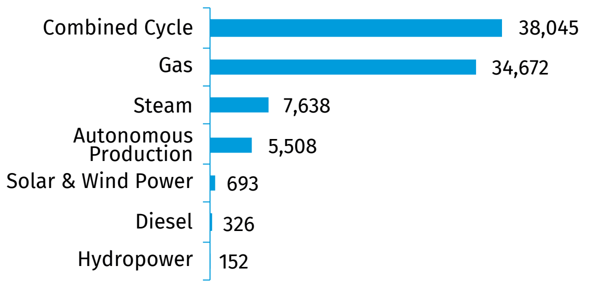
Figure 1. **Annual Electricity Generation by Source in Algeria in 2019 (GWh)**



Source: Ministry of Energy[10]

Algeria had an installed electricity capacity of 21,999 MW as of 2020.[12] This included an installed hydropower capacity of 276 MW and 400 MW of solar photovoltaics (PV), mainly off-grid.[13] According to the International Renewable Energy Agency (IRENA) statistics, in 2019, Algeria had a total renewable energy installed capacity of 686 MW (433 MW of which being off-grid). Of this, 228 MW was from hydropower, 10 MW from wind power and 448 MW from solar power (of which an estimated 25 MW was from concentrated solar power).[14] The most recent data that compare installed capacity from all energy sources are from 2018 (Figure 2).

Figure 2**. Installed Electricity Capacity by Source in Algeria in 2018 (MW)**



Source: Ministry of Energy[15]

Note: The values by source were calculated based on percentage values of the total. The Category "Other" includes installed capacity from diesel, solar power, wind power and hydropower plants.

A further 150 MW of solar PV projects, including seven sites and 15 projects of 10 MW each were released as tenders in 2019.[16] Furthermore, the state oil company Sonatrach has launched a solar expansion programme of 1,300 MW, which is to cover 80 per cent of the electricity needs for its oil facilities, of which 344 MW are already in operation.[17] A further 1,000 MW of solar PV are expected to be released as tenders in June 2021.[18]

The energy sector occupies a predominant place in the Algerian economy; hydrocarbons alone represent 60 per cent of budget revenues and 98 per cent of export revenues.[19] In 2019, following a decision to halt refining its crude oil products abroad, the country's imports of energy almost doubled compared to 2018, while exports dropped by 8.7 per cent.[10] The level of gas exports is decreasing due to rising domestic consumption and, simultaneously, decreased production, hinting at a reduced reliance on hydrocarbons for revenues in the country's future.[20] Algeria plans to reduce its dependence on hydrocarbons through a diversification of its exports and the development of renewable energy sources.[21] In addition, in July 2020 the President announced the plan to stop all imports of fuels and refined oil products by the first trimester of 2021.[22]

In 2016, 99.4 per cent of the population of Algeria had access to electricity, with approximately 400,000 people living without electricity.[23] By 2017, Algeria had reached 100 per cent electricity access.[24]

Two public companies dominate the energy market of Algeria: Sonatrach for hydrocarbon production and trade, and Sonelgaz, former public monopoly, is in charge of electricity production and distribution, as well as gas distribution. The Renewable Energy and Energy Conservation Directorate at the Ministry of Energy and Mines is responsible for the energy policy and supervises the public energy companies. The Hydrocarbon Regulatory Authority regulates the national oil products market by setting prices. The regulatory authority is the Electricity and Gas Regulation Commission (CREG). Forecasts for electricity demand are established by the state electricity and gas utility company Sonelgaz Subsidiary.

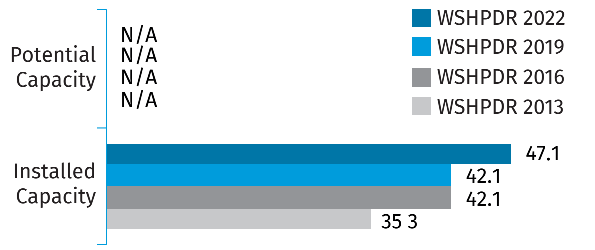
The electricity grid in Algeria has been under stress due to population growth, one-way communication, transmission losses, sudden large amounts of supply and inability of conventional sources to meet the demand.[25] To address the expected increase in electricity demand, the country is actively growing its electricity production. According to the Algerian Programme for the Development of New and Renewable Energies and Energy Efficiency–2030 (PENREE) of 2011, the country aims for an installed capacity of renewable origin of 22,000 MW by 2030, with an intermediary target of 4.5 GW by 2020.[26] The technological developments addressed by this programme include large-scale development of solar PV and wind fields, introduction of biomass fields (waste valuation), cogeneration and geothermal power and, by 2021, also development of solar thermal power (CSP). The long-term goal of this programme is to reach a 20 per cent share of renewable energy in nationwide electricity production by 2030. In contrast, the overall renewable energy target of the country is 27 per cent by 2030.[27] Hydropower is not covered by the PENREE, which favours the development of solar PV, wind power, CSP, cogeneration, biomass and geothermal sources. In fact, in 2014 the Government announced its intention to halt hydropower expansion. More recent plans announce the country's solar PV goal, set at 4 GW by 2024 and 16 GW by 2035.[20]

Electricity tariffs are separated into four categories: 1.77 DZD/kWh (0.013 USD/kWh) for consumption less than 500 kW; 4.17 DZD/kWh (0.031 USD/kWh) for 501–1,000 kW; 4.18 DZD/kWh (0.031 USD/kWh) for 1,001–4,000 kW; and 5.47 DZD/kWh (0.041 USD/kWh) for consumption over 4,000 kW.[28] As of 2021, average electricity tariffs for citizens were 4.01 DZD/kWh (0.030 USD/kWh), which is less than the real price of 5.40 DZD/kWh (0.040 USD/kWh), due to an indirect electricity subsidy.[28]

SMALL HYDROPOWER OVERVIEW

Small hydropower (SHP) in Algeria is defined as any hydropower plant with a capacity of 5 MW to 10 MW, while micro-hydropower is classified as 100 kW – 5 MW and pico-hydropower as plants of less than 100 kW.[29] As of 2020, there was at least 47.1 MW of installed SHP capacity for plants under 10 MW (Table 1). The increase in SHP capacity compared to the *World Small Hydropower Development Report (WSHPDR) 2019* is due to access to more accurate information and the inclusion of the Ighzerouftis plant, which is one of three hydropower plants making up the larger capacity Darguina hydropower plant and which was previously not counted, rather than due to an increase in capacity in recent years (Figure 3). Information on potential SHP capacity in Algeria remains unavailable.

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Algeria (MW)**



Source: *WSHPDR 2019*,[29] *WSHPDR 2013*,[30] *WSHPDR 2016*,[31] Mokrane W. & Kettab A.,[32] Bouraiou A. et al.[33]

Note: Data for SHP up to 10 MW.

The difficulty in finding up-to-date information on SHP in Algeria is likely a consequence of the Government's focus on other sources of renewable energy. According to the Ministry of Energy and Mining, 103 hydropower plants have been recorded and more than 50 plants are in operation.[34] However, an academic source cites only 23 hydropower plants as operational, with the Darguina plant, composed of three hydropower plants (Agrioun of 66 MW, Ighzerouftis of 5.2 MW and Irilemda of 24 MW), being the only one that functions regularly.[32] Approximately 21 per cent of the total hydropower installed capacity consists of SHP, but only 5.2 MW of SHP capacity, from the Ighzerouftis plant, is known to be mostly operational (Table 1).

Table 1. **List of Existing SHP Plants in Algeria (Operational and Non-Operational)**

Name	*Status**	*Location*	*Capacity (MW)*	*Head (m)*	*Launch year*
Souk el Djemaa / Michelet	Operational	Tizi Ouzou	8.1	327.0	1949
Ghrib	Operational	Ain Defla	7.0		1942
Gouriet / Maillot-aval	Needs repairs	Bouira	6.4	111.0	1949
Bouhanifia	Non-operational: no water, control table damaged	-	5.7	46.4	1978
Ighzerouftis	Operational	Bejaia	5.2	171.0	1951
Tizi Meden / Boghni-aval	Needs repairs	-	4.5	254.0	1946
Tessala	Non-operational: evacuation passage obstructed	Oran	4.2	-	-
Beni Behdel	Non-operational: no water	Telemcen	3.3	38.5	1948
Ighzerncheb-el	Needs repairs	-	2.7	-	1934

Note: *Status of hydropower plants is based on information from 2005. **Reformed plants are those that have been converted into irrigation facilities and no longer supply electricity.

Hydropower, including SHP, as an energy source plays only a marginal role in Algeria due to limited precipitation, high evaporation and competing uses for potable water. The role of hydropower in Algerian electricity production has been in steady decline since 1973, decreasing by 99 per cent from 1971 to 2015.[37] The contribution of hydropower to the total electricity production in 2019 was 0.19 per cent. The highest proportion of electricity production from hydropower was registered in 1973 at 26.80 per cent, and the lowest value ever recorded, before 2019, was 0.21 per cent in 2002.[37]

In 2014, the Government declared its intention to halt operation of electricity production from hydropower plants and to devote existing dams to irrigation and drinking water supply. The Ministry of Energy and Mining stated that the needs of the population for water supply outweighed the electricity generated by the power plants.[38] This sentiment is echoed in the New National Programme for Renewable Energy Development (2015–2030), which excludes hydropower from its roadmap.

RENEWABLE ENERGY POLICY

The renewable electricity goals of Algeria are set out as percentage values of overall electricity generation. Algeria has one of the highest economic solar power potentials in the world, estimated at 13.9 TWh/year for solar PV and 168,972 TWh/year for solar thermal power.[39] The wind power potential in the country is estimated at 35 TWh/year. Algeria has a nationwide environmental strategy, a national plan for environmental action and sustainable development (Plan national d'action environnementale et de développement durable, adopted in 2002), focusing on reducing pollution and noise, preserving biodiversity and natural spaces, training and raising of public awareness on environmental issues.

Algeria has a public procurement tendering process for renewable energy projects, which was defined by Executive Decree No. 17-98 of 26 February 2017.[40] This tendering process is intended to induce competition among investors, maximize the reductions on price per kWh of electricity produced by renewable energy sources and to avoid the risks associated with excessive profits.[34] In 2019, the Government launched tenders for the installation of solar-diesel hybrid mini-grids.[27]

Key laws pertaining to renewable energy include:

- Law No. 99-09 (28 June 1999), which set out to define the contours of renewable energy development, including hydropower;
- Law No. 02-01 (5 February 2002), which provides the legal basis for electricity management, distribution, transportation and production;
- Law No. 04-09 (14 August 2004), which provides the regulatory basis to promote renewable energy and generalize its uses, protect the environment, fight against climate change by limiting greenhouse gas emissions and preserve fossil fuels;
- Law No. 09-09 on the Finance Bill 2010, which created and determined financing for the National Fund for Renewable Energies as 0.5 per cent of oil royalties;
- Law No. 11-11 on the complementary Finance Bill 2011, which created and determined financing for the National Fund for Renewable Energies and Cogeneration as 1 per cent of oil royalties;
- Executive Decree No. 13-218 (18 June 2013) & Executive Decree No. 17-166 (2 May 2017), which determined the feed-in tariff (FIT) incentive measures to promote investment in renewable energy (premiums for the costs of diversification of electricity production from renewable energy).[41]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

In 2013, the Government of Algeria outlined details for a FIT with the aim of speeding up renewable energy development, diversifying the national energy mix and achieving its ambitious renewable energy targets. It also identified the types of technologies that would benefit from the Government aid, including solar PV, CSP, solar thermal power, hydropower, wind power, cogeneration, waste to energy and hybrid power plants. The scheme uses a premium paid per kWh above the base tariff and is expressed as a percentage of the base electricity tariff. The tariff levels vary across technologies as a function of the bonus value attributed, which is calculated based on the technology type and the percentage of the renewable energy source used in electricity generation.[42] The Government bonuses are equivalent to 100 per cent of the price per kWh of electricity for hydropower, 200 per cent for biomass and 300 per cent for waste, wind power and solar thermal power.[42]

Another financing option is the National Fund for Energy Management, Renewable Energies and Cogeneration (FNMEERC or FNER), which finances actions and projects that promote renewable energy and cogeneration. The fund also provides pre-financing for actions under the promotion of renewable energy and cogeneration.[43] Additionally, 1 per cent of oil royalties are also made available for renewable energy investments.[44] Finally, international funding is also an option. Thus, the European Union has a fund of EUR 40 million (USD 47.6 million) dedicated towards the diversification of the Algerian economy, of which EUR 10 million (USD 11.9 million) is earmarked for renewable energy and energy efficiency projects.[44]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The risks of water scarcity and the likelihood of more intense droughts in the region according to future climate scenarios indicate that further SHP development in Algeria is very unlikely. All forms of hydropower in the region are facing stagnation in potential expansion due to geographical and climatic limitations, which include: limited rainfall in the south of the country, hydropower potential concentration in limited spaces, high levels of evaporation and quick evacuation of water resources to the sea. Moreover, the Government intends to halt the production of electricity from hydropower plants, to dedicate the dams producing electricity to irrigation and to providing the population with drinking water.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Many of the hydropower dams in Algeria were built in the colonial era and have been neglected over the past years. This has led to a 99 per cent decrease in the share of hydropower in electricity production in Algeria. The key barriers to SHP development in the country include:

- Access to financing from international banks until 2015 was restricted by the Government, which led to a lack of access to financing institutions;
- Ageing and poor maintenance of existing power plants;
- Weak support for renewable energy technologies and limited knowledge resources available;
- Lack of institutional support and unstable trajectory of renewable energy policies;
- Low prices for conventional energy;
- Lack of local expertise for the realization of SHP projects.[32,33,43]

There are currently no clear enabling factors for SHP development in Algeria.

Egypt

Nadia Mohamed Eshra, Hydropower Unit, Nile Research Research Institute, National Water Research Center, Ministry of Water Resources and Irrigation; and Davy Rutajoga, International Center on Small Hydro Power (ICSHP)

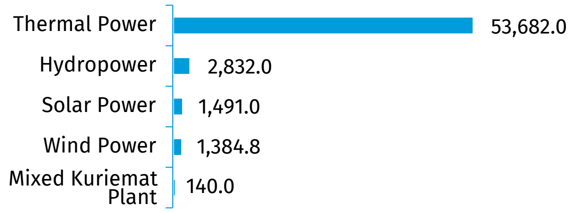
KEY FACTS

Population	105,785,785 (2022)[1]
Area	1,001,450 km^2 [2]
Topography	Egypt is divided into four major parts: the Nile Valley and Delta, which extends from the north of the valley to the Mediterranean Sea; the Western Desert, which extends from the Nile Valley to the border with Libya and from the Mediterranean in the north of Egypt to the southern borders; the Eastern Desert, which extends from the Nile Valley to the Red Sea, the Suez Canal and the Suez Gulf in the east and from Lake Manzala to the Border with Sudan; and the Sinai Peninsula, which extends from the Mediterranean in the north to the Gulf of Aqaba to the east, the Gulf of Suez and the Suez Canal to the west and Ras Mohammed to the south. The highest peak in the country is Mount Catherine, which elevates to 2,642 metres, and the lowest point is the Qattara Depression at 134 metres below sea level.[3,4]
Climate	Egypt has a dry and hot climate. It has a hot and dry season from May to September and a rather mild winter season from November to April. In coastal regions, temperatures can range between the average winter minimum of 14 °C and the average summer maximum of 30 °C. Temperatures also vary considerably in inland desert areas, particularly during the summer months when they can range from 7 °C at night to 43 °C in the morning. In winter months, the fluctuations are less dramatic, though temperatures can reach 0 °C and 18 °C in the morning. Hot wind storms, called Khamsin, sweep across Egypt between March and May carrying sand and dust and can last for days increasing the temperature by 20 °C in as little as two hours.[5]
Climate Change	Egypt has been affected by climate change and is expected to experience further increases in temperature and decreases and variability in rainfall patterns. Temperatures have been observed to increase by 0.1 °C per decade on average between 1901 and 2013 and by 0.53 °C per decade since the 1980s. Warming has been observed to increase more during the summer months than in winter by 0.31 °C and 0.07 °C per decade, respectively, since the 1960s. The daily and nightly minimum temperatures have increased throughout the country as well. Annual total precipitation has been observed to decrease by as much as 22 per cent since the 1980s, with most of the decrease observed during the winter and early spring months.[5]
Rain Pattern	Due to the arid nature of the climate, there is naturally little rainfall throughout the year with most of the rain falling along the coast, particularly in the city of Alexandria. In addition to receiving approximately 200 mm of precipitation per year, Alexandria enjoys high humidity with sea breeze-modulated moisture. The capital city of Cairo, on the other hand, receives approximately 10 mm of precipitation per year, with rainfall decreasing southwards, but enjoys humidity in the summer. The country sometimes experiences extreme sudden rainfall resulting in flash floods.[5]
Hydrology	In Egypt, the main water resource is the Nile River, which provides the country with approximately 97 per cent of the country's water requirements. The Nile is the longest river in the world, with a length of 6,650 kilometres and enters Egypt through the southern borders with Sudan and reaches to the Mediterranean. Other important water systems are the Suez Canal, the Alexandria-Cairo Waterway and Lake Nasser. The country's riverine and coastline basins can be divided into four main parts: the North Interior Basin, which covers 52 per cent of the country in the east and south-east; the Central Nile Basin, which covers 33 per cent of the country as a broad north-south strip; the Mediterranean Coast Basin, which covers 6 per cent of the country; and the North-East Coast Basin, which covers 8 per cent of the country along the Red Sea coast.[6,7]

ELECTRICITY SECTOR OVERVIEW

The main sources of electricity in Egypt are thermal power, hydropower, solar power and wind power. In 2019/2020, electricity production in the country amounted to 197,357 GWh, of which thermal power accounted for approximately 88 per cent, hydropower for less than 8 per cent, solar power for slightly more than 2 per cent, wind power for 2 per cent and isolated units and power purchased from independent power producers (IPP) accounting for less than 1 per cent (Figure 1).[8]

Figure 1. **Annual Electricity Generation by Source in Egypt in 2019/2020 (GWh)**

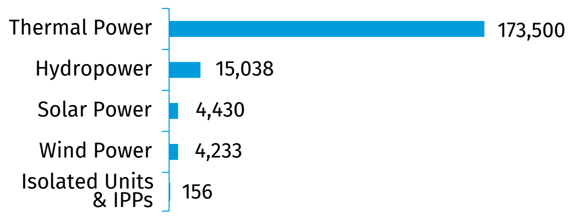


Source: EEHC[8]

In 2016, in order to meet an increasing energy demand, the Government of Egypt launched the Integrated Sustainable Energy Strategy (ISES) to 2035, an energy diversification strategy that aims to guarantee safe and stable energy supply in the country. The ISES also aims to ensure an increase of the share of renewable energy in the country's generation mix as well as to establish Egypt as a focal point of the energy map linking Africa, Europe and Asia by strengthening the interconnection of the electricity network both in the Arab region and beyond.[9]

There are six currently operational hydropower plants in Egypt, amounting to approximately 2,832 MW of installed capacity, or a 5 per cent share of the total installed capacity of approximately 59,530 MW. Thermal power, solar power and wind power account for approximately 90 per cent, 2.5 per cent and 2.5 per cent of the total installed capacity, respectively (Figure 2). Hydropower accounts for almost 5 per cent, while the joint solar/natural gas Kuriemat plant accounts for less than 1 per cent of the total installed capacity.[8]

Figure 2. **Installed Electricity Capacity by Source in Egypt in 2019/2020 (MW)**



Source: EEHC[8]

The main institutions defining energy policy in Egypt are the Ministry of Electricity and Renewable Energy (MOERE) and the Supreme Council for Energy (SCE). The MOERE regulates the generation, transmission and distribution of electricity in the country, while the Electric Utility and Consumer Protection Regulatory Agency (EgyptERA) is responsible for licensing and sector monitoring. The Egyptian Electricity Holding Company (EEHC), with its 16 companies, is responsible for system studies and planning for grid expansion and power plant projects. In terms of generation, subsidiaries are divided by regions of responsibility with the addition of the Hydro Plants Generation Company. The Egyptian Electricity Transmission Company (EETC) is responsible for the countrywide transmission of electricity to regional and local distributors with distribution companies depending on the region.[9]

The Government of Egypt has been making progress towards the development of nuclear power as part of the ISES, with plans to launch the first nuclear power plant in the country already underway as of 2021. Regulation of the nuclear power sector is to be undertaken by the Nuclear and Radiological Regulatory Authority (NRRA). The first studies on nuclear capabilities in Egypt were conducted by the Nuclear Power Plants Authority (NPPA) with technical support from the International Atomic Energy Agency (IAEA). In order to respond to the growing energy demand and accommodate the future nuclear power plants, the Government of Egypt drafted a new law, the new Electricity Law of 2015.[9]

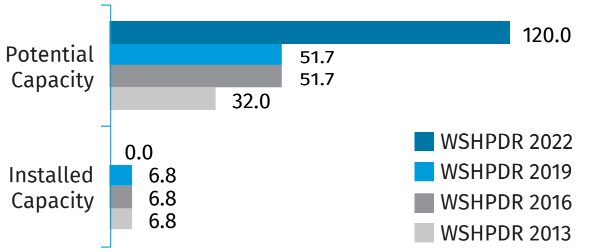
Under the New Electricity Law of 2015, the EETC is to be separated from the EEHC into an independent transmission system operator (TSO) and new companies are required to obtain a permanent licence from EgyptERA before carrying out any electricity-related activity.[10]

The electricity tariffs for residential users in Egypt in 2020/2021 ranged from USD 0.075 per kWh for low consumption (less than 100 kWh/month) to USD 2.260 per kWh for high consumption (more than 1,000 kWh/month).[8] The electrification rate in the country was 100 per cent in 2019.[11]

SMALL HYDROPOWER SECTOR OVERVIEW

In Egypt, there is no official definition of small hydropower (SHP). For this chapter, SHP will be defined as hydropower plants with a capacity of up to 10 MW. Currently, there are no operational SHP plants in Egypt, whereas the total potential capacity is estimated to be at least 120 MW.[12] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, potential capacity increased based on more accurate data and installed capacity decreased taking into account the non-operational status of the plants (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Egypt (MW)**



Source: Eshra,[12] *WSHPDR 2019*,[13] *WSHPDR 2016*,[14] *WSHPDR 2013*[15]

Table 1. **List of Selected Potential Small Hydropower Projects in Egypt**

Name	*Average potential capacity (MW)*
Damietta	9.00
Rosetta	5.30
Zefta	3.53
El-Tawfeki	2.02
El-Menofi	1.83
Tamia	1.10
El-Azab	0.80
Mokthalat	0.50

Source: Eshra et al.[16]

In Egypt, SHP started in the 1890s with the launch of the 1.1 MW Tamia plant and the 0.8 MW El-Azab plant. They were followed by the 5 MW Old Nag Hamadi plant installed in Upper Egypt and after a long period of time by the 5 MW El-Lahoun plant in Fayum Oasis. All these plants stopped operating due to different problems.

In 2019, studies by Eshra et al. identified eight potential sites for the development of SHP in the Nile Delta and Fayum Oasis (Table 1). The sites have an estimated 24.08 MW of combined potential capacity and an estimated generation capacity of 15.6 GWh.[16] A 2019 study of the same area by the Hydroelectric Power Plant Executive Authority (HPPEA) identified at least seven potential sites for the development of SHP. The Ministry of Electricity plans to develop sites with an estimated potential capacity of 2–5 MW. The construction of the plants is to be funded by the German development agency KfW with a budget of approximately USD 32,620,950. As of 2020, the project had yet to be validated by the Ministry of Irrigation due to concerns over the environmental and social impact of the project in the region.[17]

RENEWABLE ENERGY POLICY

The Government of Egypt issued an environmental law in 1994 to accord special attention to environmental concerns in its energy policy. Following the adoption of this law, the Egyptian Environmental Affairs Agency (EEAA) was created to develop, monitor and implement pilot energy projects. The EEAA is endowed with authority to review and approve all environmental impact assessments (EIA) that must be submitted before licensing power plants in Egypt.[9]

In 2015, partly due to a need for a more competitive and less centralized system, the Government of Egypt adopted the new Electricity Law 87/2015, which emphasized the importance of renewable energy. This new law came after the adoption of the Renewable Energy Law (REL) 203/2014, which aimed to encourage the private sector to invest in renewable energy. Provisions made to specifically address the private sector and facilitate its involvement in renewable energy are outlined in Article 2 of the REL, which includes feed-in tariffs (FITs), competitive bids and independent power production through third party access.[10]

In 2014, the Government of Egypt announced a FIT programme aiming to add approximately 4.3 GW of generation capacity from renewable energy sources. Divided into two rounds, the FIT programme was introduced by the Cabinet Decrees No. 1947 of 2014 and No. 2532 of 2016 for rounds 1 and 2, respectively. These rounds set tariffs for the electricity generated from wind and solar power to be applicable for two years for round 1 and one year and a half for round 2 on power purchase agreements (PPAs) concluded after the issuance of decrees. The PPAs should not exceed 20 years for wind power projects and 25 years for solar power projects.[10]

Under the competitive bid scheme outlined in the REL, the New and Renewable Energy Authority (NREA) issues tenders to private companies that are to install renewable energy power plants, including SHP plants, via an Engineering, Procurement and Construction (EPC) contract. The electricity produced shall be sold to ETTC at a price suggested by Egypt ERA and approved by the Cabinet.[10]

Though there are no government incentives that specifically target hydropower, the African Development Bank's Electricity and Green Growth Support Program (EGGSP) to the Government of Egypt offered a loan of approximately USD 244,698,750 to the country to support its renewable energy and climate change mitigation initiatives. This loan could apply to the hydropower development efforts currently undertaken by the HPPEA.[18]

As part of the Government of Egypt's support for the development of renewable energy, the new Investment Law No. 72 of 2017 was adopted to offer incentives and tax reductions for investors in renewable energy projects. The incentives for renewable energy projects include flat custom duty rates on all machines and equipment for renewable energy projects, registration fee waivers, discounts for project investments, value-added tax (VAT) exemptions for renewable electricity activities and reductions for imported renewable energy equipment, flat electricity rates until 2025, waste-to-energy tariffs and a net-metering scheme. There were also plans for lifting electricity subsidies adopted by the Prime Ministerial Decree 1257/2014, which was delayed due to the COVID-19 pandemic and instead expected to be achieved in the fiscal year 2024/2025.[10]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The development of new SHP projects in Egypt is hampered mainly by:

- The lack of government interest and the favouring of a renewable energy policy based largely on wind and solar energy. Without any financial incentives being given specifically to SHP, it will be difficult to attract investment over other more favourable renewable energy options;
- More studies of the SHP potential should be carried out. The lack of interest in SHP stems from a general consensus that some 85 per cent of the Nile River has already been developed for hydropower, meaning that the NREA stands to make better marginal gains and garner better financial support by looking into other untapped non-hydropower resources. Nonetheless, this assessment is largely based on a perspective from large hydropower projects. More accurate studies on SHP may reveal the existence of significant undeveloped potential.

Enablers for SHP development in Egypt include:

- The Government's strategy to position Egypt as an energy hub that connects Africa, Asia and Europe involves the increase in the share of renewable energy in the generation mix;
- Relatively recent laws and policies that centre renewable energy could lead the Government to consider alternative ways of generating electricity, including SHP;
- The relatively recent emphasis on renewable energy incentives as well as encouragement of international investors and the private sector's involvement in the energy sector could attract actors interested in SHP development;
- Significant SHP potential remains undeveloped and is especially high in parts of the country with a developed irrigation network and various types of hydraulic constructions.

Morocco

Bilal Amjad, International Center on Small Hydro Power (ICSHP)

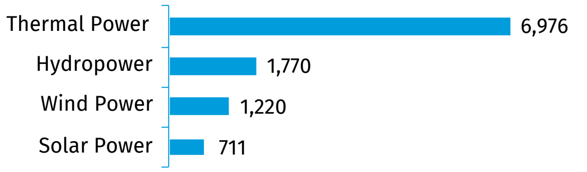
KEY FACTS

Population	36,280,141 (2021)[1]
Area	446,550 km^2 [2]
Topography	Morocco has four mountain ranges. The Rif Chain extends in an arc parallel to the Atlantic Ocean in the west. The High Atlas, approximately 80 kilometres in breadth, extends eastwards for 700 kilometres. Mount Toubkal is the highest point of the massif (4,165 metres). The Middle Atlas and Anti Atlas are the other two massifs. Beyond the chains of the Atlas, lie the pre-Saharan and Saharan zones of the country, where large hamadas form rugged desert plateaus covered with pebbles or dunes.[2]
Climate	Morocco is characterized by a diverse climate. In the northern coastal regions, temperatures are generally mild, reaching an average of 14 °C. In the highlands and mountains, temperatures are usually below 0 °C but can reach -20 °C, causing frost on the plateaus and significant snowfall in the mountains. Summers are hot and dry with mean temperatures of 24 °C on the coast and above 35 °C, sometimes exceeding 40 °C, in the country's interior.[2]
Climate Change	The climate in Morocco is very vulnerable to the global temperature rise, particularly on the north-eastern coast where the sea level is predicted to rise by up to 59 centimetres by the end of the 21st century, causing flooding and storm surges. According to the National Meteorological Directorate of Morocco, by 2100 the average temperature can increase by 2–5 °C and rainfall can decline by 20–30 per cent. These shifts will have a big impact on the country's water resources, leading to less precipitation and more frequent droughts.[3] The year 2020 was recorded among the country's four driest years since 1981. The annual mean temperature across the country in 2020 was 1.4 °C warmer than during the period between 1981 and 2010.[4]
Rain Pattern	In the north, winters are generally wet and mild, with the cumulative annual rainfall decreasing from north to south (from 1,000 to 200 mm/year) and peaking in the mountainous regions (2,000 mm/year in the Rif and 1,800 mm/year in the Middle Atlas). In the southern regions, rainfall is very rare and irregular. Most regions on average receive less than 130 mm of rain per year, with the exception of rare humid, tropical air surges, which give rise to rainfall in the form of showers.[2]
Hydrology	The most important and permanent rivers of Northern Africa are in Morocco: Loukos (100 km), Sebou (500 km), Bouregreg (250 km), Moulouya (450 km), Daraa (1,200 km), Oum Rbia (600 km), Tensift (270 km) and Ziz (270 km).[2]

ELECTRICITY SECTOR OVERVIEW

Compared with other countries in the Middle East and Northern Africa, Morocco is characterized by a lack of conventional hydrocarbon resources and a high reliance on energy imports.[5] In 2019 electricity generation in Morocco totalled 40,348 GWh, of which approximately 67 per cent was from coal, almost 12 per cent from natural gas and wind power each, 4 per cent from hydropower and solar power each and the rest from other sources (Figure 1).[6] National electricity production in 2019 accounted for nearly 99 per cent of total electricity demand, while the remainder was imported through interconnections with neighbouring countries including Spain and Algeria. The same year 1,453 GWh of electricity was exported, which was more than three times higher than the year before.[6]

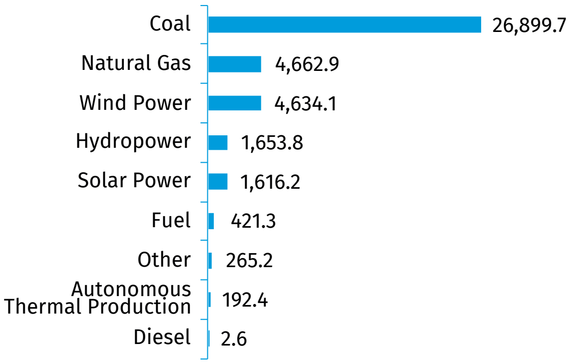
Figure 1. **Annual Electricity Generation by Source in Morocco in 2019 (GWh)**



Source: ONEE[6]

In 2019, the installed electricity capacity of Morocco was 10,677 MW. Of the total, thermal power plants accounted for 65 per cent, hydropower plants for 17 per cent, wind power plants for 11 per cent and solar power plants for 7 per cent (Figure 2).[7]

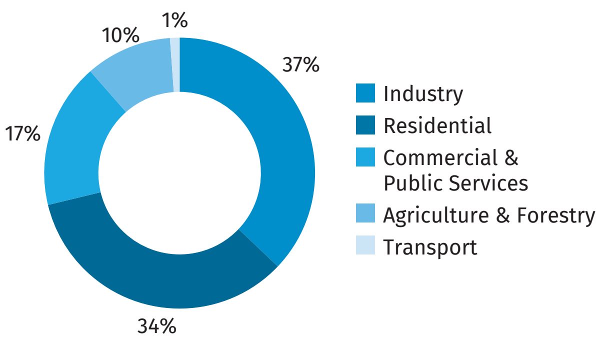
Figure 2. **Installed Electricity Capacity by Source in Morocco in 2019 (MW)**



Source: ONEE[7]

Total energy consumption in Morocco has significantly increased in recent years. Thus, in 2019, it grew by 9 per cent compared to 2018, driven by growth in electricity consumption, which increased by 15 per cent due to the progress achieved in rural electrification and economic growth.[6,8] Between 2015 and 2030, primary energy consumption in the country is projected to double and electricity demand is expected to increase 2.5 times.[5] Overall, since 1990, the electricity sector of Morocco has developed impressively by diversifying generation, improving security of supply and reaching almost universal access to electricity.[9] Currently, electricity consumption in the country is dominated by the industrial and residential sectors (Figure 3).[10]

Figure 3. **Electricity Consumption by Sector in Morocco in 2018 (%)**



Source: IEA[10]

The electricity sector in Morocco is dominated by the state-owned operator, the National Office of Electricity and Potable Water (ONEE). It has the status of the single buyer of electricity produced in the country, except for generation from renewable sources, for which a specific law allows private-to-private electricity transactions.[11] ONEE owns the entire transmission network and much of the distribution network and can give concessions to private operators through purchase guarantees.[12] As the sole buyer, ONEE supplies the national market through its own plants, those of independent power producers (IPPs) and through a number of private industrial producers. IPPs include some of the largest plants in the country such as Jorf Lasfar Energy Company (JLEC) (coal), Safi Energy Company (SAFIEC) (coal) and Electrical Energy Company of Tahaddart (gas, combined cycle).[13]

The Moroccan electricity grid is linked with the Spanish grid through a 400 kV double underwater alternating current line under the Strait of Gibraltar with a capacity of 1.4 GW. Since 1988, Morocco has also had a synchronous interconnection with the Algerian grid via a 400 kV transmission line. Initially its capacity was 1.2 GW, but increased to 1.7 GW with the installation of a second and third lines in 2009.[13,14]

Until 1995, only 18 per cent of the Moroccan population had access to electricity and over the last 20 years approximately 12 million citizens received access through the Global Rural Electrification Programme. Today the electrification rate in Morocco is close to 100 per cent. The country adopted a utility-lead electrification programme where ONEE was responsible for achieving rural and remote area electrification targets. Strong political support, involvement of local stakeholders, funding and engagement of the private sector have enabled ONEE to provide sustainable electricity from solar power to 200,000 households in remote rural communities.[6] In 2019, 373 villages were electrified, providing electricity access to 10,113 households.[6,11]

Electricity tariffs are not uniform in Morocco. The customers are subject to tariffs that are set and reviewed by the Ministry of General Affairs and Governance, on the advice of an Inter-Ministerial Pricing Committee. The latest review process was undertaken between 2014 and 2017. The tariffs are applied to distribution companies by ONEE and to final costumers by distribution companies and depend on the consumer category.[15] Tariffs applied to households are incremental based on monthly consumption, ranging from 0.10 USD/kWh for consumption below 100 kWh to 0.18 USD/kWh for consumption above 500 kWh.[16] A bi-hourly tariff aiming to reduce the evening peak demand is implemented by ONEE on the national level to all low-voltage consumers (including domestic, industrial and agricultural users) with monthly electricity consumption exceeding 500 kWh.[17] Electricity consumption for public lighting and by administration buildings is subject to a fixed price tariff.[15] Rural populations are subjected by ONEE to pricing based on a prepaid meter. These rates, depending on the type of use and consumption bracket, fluctuate between 0.12 USD/kWh and 0.20 USD/kWh.[18]

Multiple changes have been experienced in the electricity sector of Morocco over the past years due to the competitive production and commercialization of electricity from renewable energy sources, for very high-voltage/high-voltage/medium-voltage (MV) customers, in accordance with Law 13-09 on renewable energy. The creation of a regulatory agency, National Energy Regulatory Agency (ANRE), was announced by Law 48-15 adopted in 2016.[19] ANRE is responsible for ensuring equal access to the national electricity grid, setting tariffs for the use of the transmission and transportation grids, approving rules and tariffs for access to electricity interconnections and accompanying the implementation of the national energy transition strategy.[20]

SMALL HYDROPOWER SECTOR OVERVIEW

In accordance with the classification established by the International Union of Electric Power Distributors, four categories of hydropower plants are distinguished in Morocco: pico- (less than 20 kW), micro- (20–500 kW), mini- (500–2 MW) and small hydropower plants (SHP) (2–10 MW).[21] The current chapter uses the definition of SHP as all hydropower plants up to 10 MW.

As of 2021, the total installed capacity of SHP up to 10 MW in Morocco was estimated at 30.5 MW (Table 1).[22,23,24] The decrease compared to the *World Small Hydropower Development Report (WSHPDR) 2019* is due to access to more accurate data (Figure 4). The potential capacity is estimated at 300 MW, which is also slightly lower than reported in the *WSHPDR 2019*, with the decrease also being based on a more accurate estimate.[25]

Source: ONEE,[22] Saad Alami,[23] Government of Morocco[24]

In the 1990s, the Development Centre of Renewable Energies (CDER) identified 153 potential SHP sites in the regions of Haouuz, Khenifra and Chefchaouen. The combined potential capacity of these sites was estimated at 6.7 MW, with individual sites having capacities up to 500 kW.[29] More recently, the ONEE has identified 125 sites suitable for SHP development in the basins of the Oum-Errabia, Sebou and Moulouya Rivers, with individual capacities ranging between 100 kW and 1.5 MW and a total potential capacity estimated at 300 MW.[25] Due to the unavailability of lists of the sites identified in these studies, it is not possible to establish whether any overlaps between the two exist, therefore, the current chapter uses the findings of the more recent study as the SHP potential estimate.

Large hydropower has played an important role in the country's energy mix since the 1960s, however, a large share of the available potential has been developed. Therefore, as part of the Government's strategy to promote renewable energy sources by 2030, the main focus for hydropower lies with pumped-storage hydropower as well as small-scale projects.[30] Furthermore, many studies show concern about the impact of climate change on the availability of water in Morocco, which may affect the SHP potential in future.[31] Under Law 13-09 on renewable energy, a number of hydropower projects were approved for development by the private sector.[30] One of these projects consisted of the rehabilitation of an SHP plant at Flilou by the private company Energie Terre; the project was commissioned in 2015.[23] A further 11 SHP projects up to 10 MW with a combined capacity of 61.5 MW are currently under development (Table 2) as well as 10 other projects with capacities between 11.7 MW and 30 MW.[32]

Source: MEME[32]

ONEE has also initiated a project for the rehabilitation of existing hydropower capacities with an estimated cost of approximately EUR 35 million (USD 41 million) to be financed through a loan from the European Bank for Reconstruction and Development (EBRD). The project includes rehabilitation of such SHP plants as Taurart, Bouareg, Taza, Askaw, Sefrou, Tabant and Fes Aval as well as a study of the generation potential of the country's hydropower fleet, including the impacts of the climate crisis.[33]

RENEWABLE ENERGY POLICY

In 2009, Morocco adopted a National Energy Strategy (NES) as a roadmap for the transformation of the energy sector towards greater sustainability, efficiency and financial stability. The NES sets five key objectives for the country's energy policy, including: 1) diversification of the energy mix, 2) national resource development including renewable energy resources, 3) improvement of energy efficiency, 4) integration with international and regional (European and African) energy markets and 5) industrial integration of renewable energy and green technologies.[34]

The climate action strategy of Morocco is defined by the Climate Change Policy (March 2014), the National Sustainable Development Strategy (November 2017) and the Nationally Determined Contribution (NDC) to the United Nations Framework Convention on Climate Change (UNFCCC) (2016). On 21 September 2016, Morocco signed the Paris Agreement, committing to cut its greenhouse gas emissions by 17 per cent by 2030, with an additional reduction of 25 per cent on the condition of international support.[34] The country intends to raise the share of renewable energy sources in its total installed capacity to 52 per cent by 2030. The 2016–2030 period will therefore see the development of 10,100 MW of renewable energy, with solar power to account for 20 per cent of the 2030 energy mix, wind power for 20 per cent and hydropower for 12 per cent. Moreover, Morocco is committed to achieving 15–20 per cent energy saving by 2030 through energy efficiency programmes for the industrial and transport sectors. These strategies are aiming to ensure the country's energy independence, reduce its greenhouse gas emissions and diversify the energy mix.[9,31]

Since 2008, Morocco has experienced a period of rapid change in its power sector, focusing on harnessing its huge renewable energy potential. In order to ensure meeting the energy transition targets, the renewable energy sector of Morocco has been undergoing liberalization. In 2008, Law 16-08 raised the threshold for the allowed self-generation capacity from 10 MW to 50 MW and allowed operators to sell ONEE their occasional surpluses. Law 13-09 promulgated in 2010 set out the legislative framework for the promotion of renewable energy sources. The law allowed renewable electricity producers to feed electricity into the medium- and high-voltage grid or sell it to users. It also removed the power limitations for certain types of energy and introduced three licensing regimes for renewable energy projects depending on the size: a free regime for capacities below 20 kW; a declaration regime for capacities between 20 kW and 2 MW; and an authorization regime for projects above 2 MW. This law was amended by Law 58-15 and Law 13-09, allowing independent renewable energy producers (including hydropower plants above 30 MW) to sell electricity surpluses to ONEE or a distribution system operator. These measures will enable clients from the tertiary and residential sectors to develop renewable energy capacities and feed any excess production into the low-voltage network.[31] At the moment of writing of the current chapter, two further draft laws were under consideration — draft Law 40-19 and a draft law on self-generation. These aim to improve the legislative and regulatory framework for renewable energy and self-generation projects.[35]

In line with the national energy transition strategy, in 2021 the Ministry of Energy, Mines and Environment agreed to collaborate with the International Renewable Energy Agency (IRENA) on accelerating the energy transition and advancing the national green hydrogen economy, as Morocco intends to become a major producer and exporter of green hydrogen.[36]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

There are multiple barriers to SHP development in Morocco. Some of the most important ones are the following:

- SHP projects are less attractive in comparison to other renewable energy sources such as solar and wind power, for which the investment returns are higher;
- Lack of public awareness about the benefits of SHP;
- Low level of interest in research and development (R&D) projects on SHP at universities;
- Impact of the climate crisis on the availability of water resources.

Despite the above barriers, opportunities for SHP development in Morocco exist due to the following factors:

- Availability of data on potential sites for SHP development;

- The policy, legislative and regulatory frameworks favour renewable energy projects, including hydropower.

Sudan

International Center on Small Hydro Power (ICSHP)

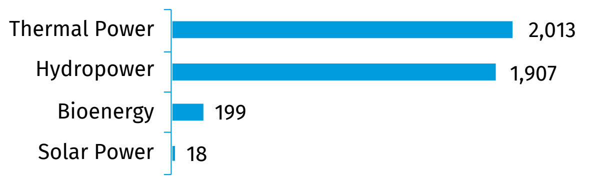
KEY FACTS

Population	43,849,269 (2020)[1]
Area	1,849,234 km^2[2]
Topography	Sudan is a large country mainly composed of plains and plateaus drained by the Nile River and its tributaries. Northern Sudan is largely covered with a sandy desert diversified by steep-sided granite hills. South-central Sudan is marked by isolated hills that culminate in the Nuba Mountains. The north-east of the country borders the Red Sea, while the Darfur Plateau in the west carries the Marrah Mountains culminating at 3,042 metres above sea level.[3]
Climate	Sudan has a hot, desert climate with strong winds prevailing all year long in the north, bringing dry and cool air in the winter. In the summer, temperatures often exceed 43 °C in the north. the southern regions are slightly cooler. The mean annual temperatures in the country are between 26 °C and 32 °C.[3,4]
Climate Change	Sudan has been experiencing the effects of global warming including increasingly frequent extreme climatic events. Droughts are more common and rainfall has become even more erratic. Temperatures were observed to increase by 0.2-0.4 °C per decade between 1960 and 2009, while precipitation decreased by 20-30 mm per decade in the same time frame. By 2050, temperatures are projected to increase by as much as 3 °C and the Red Sea levels are expected to increase by 30-50 cm.[5]
Rain Pattern	Sudan has a rainy season from March to October, with most of the rainfall occurring between June and September. Rainfall in the country is generally unpredictable and unreliable, with the northern regions experiencing little to no rainfall (less than 50 mm of rainfall). Central regions receive between 200 mm and 700 mm of rainfall a year, while the southern regions enjoy more rainfall at over 1,500 mm per year.[4]
Hydrology	Sudan enjoys considerable water resources primarily from the Nile River and its tributaries, as all rivers and streams of the country drain into or towards the Nile. The White Nile and the Blue Nile enter the country from the south-east and join at Khartoum and after the confluence flow northwards as the Nile.[4]

ELECTRICITY SECTOR OVERVIEW

The main sources of electricity in Sudan are hydropower and non-renewable thermal power. Of the total 16,846 GWh generated in Sudan in 2019, hydropower accounted for almost 61 per cent and thermal power for 39 per cent. Bioenergy and solar power accounted for 109 GWh and 22 GWh, or 0.7 per cent and 0.1 per cent, respectively, of the total electricity generation (Figure 1).[6]

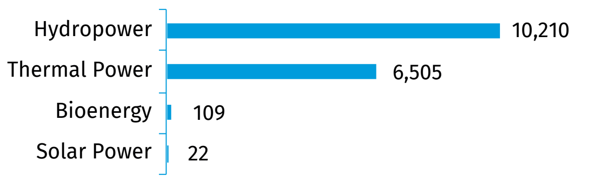
Figure 1. **Annual Electricity Generation by Source in Sudan in 2019 (GWh)**



Source: IRENA[6]

Sudan has one of the largest power sectors in Sub-Saharan Africa and was one of the largest crude oil producers in the region until 2011 when South Sudan gained independence. In addition, South Sudan also retained custody of most of the hydropower plants that once served the former unified country. This meant a significantly reduced installed capacity for the Republic of Sudan.[7,8]

Figure 2. **Installed Electricity Capacity by Source in Sudan in 2020 (MW)**

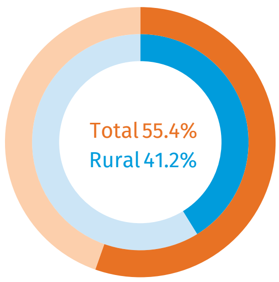


Source: IRENA[6]

In 2020, Sudan had a total installed electricity capacity of 4,137 MW, of which non-renewable thermal energy, hydropower and bioenergy represented almost 49 per cent, 46 per cent and 5 per cent, respectively. Solar power accounted for 18 MW, or 0.4 per cent, of the total installed capacity (Figure 2).[6]

In 2020, Sudan had a total electrification rate of 55 per cent, with a rural electrification rate of 41 per cent (Figure 3).[9,10]

Figure 3. **Electrification Rate in Sudan in 2020 (%)**



Source: World Bank[9,10]

The energy sector in Sudan is overseen by the Ministry of Energy and Petroleum (MoEP) and is composed of five major companies: the Sudan Electricity Holding Company (SEHC), the Sudan Electricity Transmission Company (SETC), the Sudan Electricity Distribution Company (SEDC), the Sudan Thermal Power Generation Company (STPG) and the Sudan Hydro and Renewable Energy Company (SHREC). These companies do not have financial autonomy and are integrated into the MoEP. The MoEP also oversees the Electricity Regulation Authority (ERA), which regulates the country's electricity sector.[7]

The electricity generated in Sudan is mostly publicly-owned with the exception of some thermal generation in isolated grids and emergency powership rentals operated by independent power producer (IPPs). With most of the crude oil reserves owned by South Sudan after the separation, Sudan has had to adapt to meet its ever-growing electricity demand. This includes international agreements for the importation of electricity from neighbouring countries.[7]

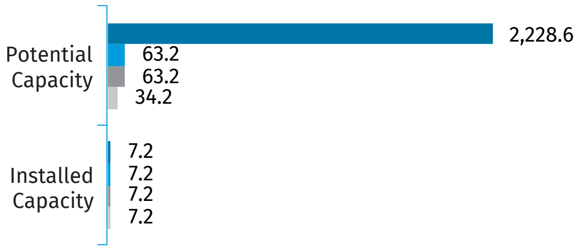
Sudan has one of the lowest electricity tariffs in the region. In January 2021, the average tariff was 0.023 USD/kWh, with the bill collection rate standing at 93 per cent.[7]

SMALL HYDROPOWER SECTOR OVERVIEW

The Government of Sudan defines small hydropower (SHP) as hydropower plants with an installed capacity between 500 kW and 5 MW. Mini-hydropower is defined as 50–500 kW plants and micro-hydropower is below 50 kW. For the purpose of this chapter, the up to 10 MW definition of SHP will be used.

There is currently one SHP plant in Sudan, the El-Girba 2, which has an installed capacity of 7.2 MW (Figure 4).[11] The estimated technical SHP potential in Sudan is 2,228.6 MW, including 123.2 MW from 352 sites of 0.1–1 MW capacity and 2,105.4 MW from 435 sites of 1–10 MW capacity.[12] The increase in SHP potential compared to the *World Small Hydropower Development Report (WSHPDR) 2019,* is due to the more recently obtained data from a study on SHP potential in Sub-Saharan Africa. The installed capacity has remained unchanged (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Sudan (MW)**



Source: Korkovelos et al.,[12] *WSHPDR 2019,*[13] *WSHPDR 2016,*[14] *WSHPDR 2013*[15]

RENEWABLE ENERGY POLICY

Sudan does not have an integrated renewable energy policy document. However, the country has been making efforts to formulate plans to develop its renewable energy potential. While hydropower represents approximately 60 per cent of the total electricity generated in the country, the Government of Sudan is committed to further integrate other renewable energy sources into the generation mix. Specifically, the Government aims to have at least 50 per cent of electricity generation from other renewable energy sources than hydropower by 2031.[16]

The Government also adopted a National Energy Efficiency Action Plan (NEEAP) in 2013 after becoming a member of the Regional Center for Renewable Energy and Energy Efficiency (RCREEE). The set aims include achieving universal electrification, doubling the rate of energy efficiency improvement and ensuring access to modern and reliable electricity by 2030. The Government is also committed to developing the country's SHP potential for a total installed grid-connected capacity of 50 MW by 2030.[16,17]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

SHP plants are regulated by the same legislation as larger hydropower projects. The main legislation and regulation documents in Sudan concerning hydropower projects are:

- The Water Resources Act (1995);
- The National Water Act (2007);
- The Sudan Electricity Act (2001).

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The development of new SHP projects in Sudan is hampered mainly by:

- Lack of a comprehensive renewable energy policy that addresses SHP;
- The Government's focus on larger hydropower to solve the country's electrification issues;
- Irregularity of rainfall patterns, which affects SHP development, further exacerbated by climate change;
- Lack of comprehensive mapping of renewable energy sources in key areas;
- Most of the electricity generation is state-owned, which might discourage potential private sector investors.

Enablers for the development of SHP projects include:

- The abundant water resources in the country due to the location in the Nile Basin. There is great potential for SHP development;
- The Government's commitment to developing renewable energy sources and the inclusion of SHP in 2030 energy development goals.

Tunisia

Nouri Chtourou, Emna Omri, Rim Jemli and Soukaina Fersi, University of Sfax

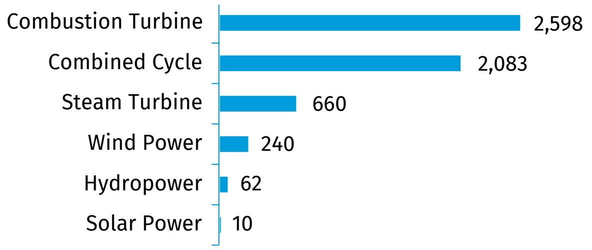
KEY FACTS

Population	11,708,370 (2020)[1]
Area	155,360 km^2 [2]
Topography	The country is divided into three distinct regions. The northern region is characterized by mountains, cork forests and grasslands. The central region is a semi-arid steppe plateau with olive groves. The southern region, which stretches from the border with Algeria to the Mediterranean, contains date palm oases and saline lakes. The extreme south of Tunisia merges into the Sahara Desert. The highest point, Jebel Chambi (1,544 metres), is located near the city of Kasserine.[2]
Climate	The north of Tunisia benefits from a Mediterranean climate, the centre and the Gulf of Gabes have a semi-arid climate and the rest of the country has a desert climate.[2]
Climate Change	The National Institute of Meteorology of Tunisia projects that, based on the climate scenario “RCP4.5”, climate in the country by 2050 and 2100 will be characterized by an increase in average annual temperatures and a decrease in annual precipitation. The rise in temperatures will vary between 1 °C and 1. 8°C by 2050 and between 2 °C and 3 °C by the end of the 21st century. In addition, there will be a decrease in annual precipitation of between 5 and 10 per cent by 2050, with a further decrease of between 5 and 20 per cent by 2100.[3]
Rain Pattern	Rainfall is between 400 mm/year in the north of the country and 1,500 mm/year in the far northwest. The central region of Tunisia receives 200–400 mm/year, while in the southern regions of the country rainfall is rare, averaging approximately 50–200 mm/year.[4]
Hydrology	The most important river system in Tunisia, the Medjerda (460 km long), rises in Algeria and drains into the Gulf of Tunis. It is the only river in the country that flows perennially; other watercourses fill only seasonally. In the central Tunisian steppes, after heavy rains, occasional waterways flow southwards out of the Dorsale Mountains, but evaporate in salt flats without reaching the sea.[4]

ELECTRICITY SECTOR OVERVIEW

The electricity sector in Tunisia is characterized by a steady rise in demand and a decrease in the availability of national resources. In 1999, net imports of electricity stood at 6,978 GWh. Since 1999, there has been a steady increase in electricity imports, reaching 72,106 GWh in 2018.[5] Electricity generation rose from 19,245 GWh in 2018 to 20,217 GWh in 2019. Of this total, 17,007 GWh was provided by the Tunisian Company of Electricity and Gas (STEG), 3,071 GWh by the Carthage Power Company (CPC) and 139 GWh by autoproducers.[6] The electricity sector primarily uses natural gas, which accounts for more than 90 per cent of electricity production (Figure 1).

Figure 1. **Annual Electricity Generation by Source in Tunisia in 2019 (GWh)**

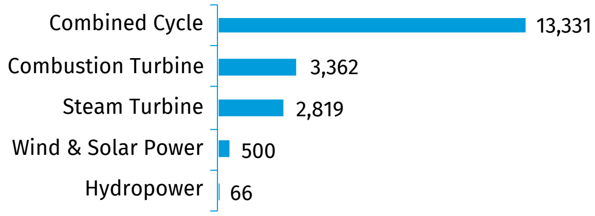


Source: STEG[6]

Note: Includes generation by STEG and CPC only.

Installed electricity capacity in Tunisia increased from 5,076 MW in 2018 to 5,653 MW in 2019. The national generation capacity is composed of steam turbines, gas turbines and combined cycle power plants. The share of wind power, solar photovoltaics (PV) and hydropower in the country’s energy mix is very insignificant compared to the available potential of those three resources (Figure 2).[6]

Figure 2. **Installed Electricity Capacity by Source in Tunisia in 2019 (MW)**



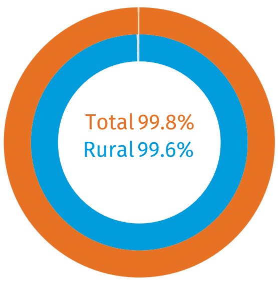
Source: STEG[6]

Note: Does not include installed capacity for hydropower plants not connected to the national grid (approximately 5 MW).

Tunisia is heavily dependent on fossil fuel imports, in particular, imports of natural gas from Algeria. The continuous volatility of fossil fuel prices and the increase of net energy imports have had significant negative repercussions for the country's economy, including massive outflows of foreign currency and an increase in public spending. An important feature of the energy sector of Tunisia are the vast subsidies allocated to conventional energy in order to keep the tariffs for hydrocarbons and electricity at a level that would not deteriorate the purchasing power of the poorest groups of the population. In fact, the budget allocated to energy subsidies tripled between 2017 and 2020, increasing from TND 650 million (approximately USD 239 million) in 2017 to TND 1,880 million (approximately USD 693 million) in 2020.[7]

In 2019, the total length of medium-voltage (MV) and low-voltage (LV) lines in the electricity transmission network of Tunisia reached 180,419 km, with 60,966 km of MV lines and 119,453 km of LV lines. This represented a combined extension of an additional 5,030 km (a 2.9 per cent increase) relative to 2018. The length of the high-voltage network reached 6,985 km in 2019.[6] In 2019, the total national electrification rate was at 99.8 per cent, while the rural electrification rate stood at 99.6 per cent (Figure 3).[8]

Figure 3. **Electrification Rate in Tunisia in 2020 (%)**



Source: STEG[8]

The main actor in the country's electricity sector is the state-owned STEG, which is responsible for electricity generation and distribution. The Tunisian electricity market is partially liberalized. Following Decree 1996-1125 (1996) and Law 96-27 (1996), private generation of electricity is possible through concessions granted by state authorities. This also includes off-grid sources.

Electricity prices at all levels are set at the end of each fiscal year by the Ministry of Industry in collaboration with relevant Government agencies such as the General Direction for Energy (DGE), the Tunisian Enterprise of Petroleum Activities (ETAP), the Tunisian Company of Refining Industries (STIR), the Ministry of Commerce and the Ministry of Finance. Prices are influenced by numerous factors, including the international prices of crude oil and gas, the financial situation of the STEG, ETAP and STIR, as well as the level of Government subsidies. After the STEG's price policies have been approved by the Government, the Ministry of Industry sets consumer gas and electricity prices.

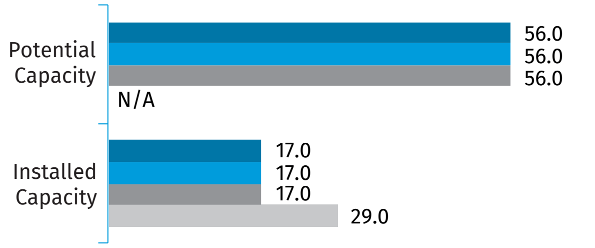
Since June 2019, STEG has applied new electricity tariffs. For low-voltage consumers, tariffs are assigned based on monthly consumption for households and other consumers and according to time slots in the case of pumping for agricultural irrigation. For the category that consumes between 1 and 100 kWh of electricity per month, the tariffs differ between households and other consumers. For households that consume between 1 and 50 kWh/month, the price per kWh is TND 0.062 (USD 0.023). For households that consume between 51 and 100 kWh/month, the price per kWh is fixed at TND 0.096 (USD 0.036). For consumers exceeding 100 kWh/month, the price per kWh varies between TND 0.176 (USD 0.065) and TND 0.414 (USD 0.15) for households and between TND 0.195 (USD 0.072) and TND 0.391 (USD 0.15) for other consumers. For the category of agricultural irrigation, the price varies between TND 0.106 (USD 0.039) and TND 0.391 (USD 0.15) according to three time slots (day, night and evening peak).

The tariffs applied to MV and HV consumers are assigned according to the type of consumer and four time slots (day, summer morning peak, evening peak and night). For MV tariffs, the prices per kWh are assigned according to four categories: regular category (TND 0.251 (USD 0.092)), time slots category (TND 0.188–0.366 (USD 0.069–0.130)), pumping water for agricultural irrigation (TND 0.138–0.195 (USD 0.050–0.071)) and relief supply (TND 0.200–0.407 (USD 0.073–0.150)). For HV tariffs, the prices per kWh are categorized into two types: time slots category (TND 0.160–0.309 (USD 0.058–0.110)) and relief supply (TND 0.168–0.350 (USD 0.061–0.130)). It should be noted that the above-mentioned tariffs do not include the Value Added Tax rate of 19 per cent and the municipal surcharge of TND 0.005/kWh (0.002 USD/kWh).[9]

SMALL HYDROPOWER SECTOR OVERVIEW

There is no official definition of small hydropower (SHP) in Tunisia. For the purposes of this chapter, the definition of up to 10 MW will be used. The installed capacity of SHP up to 10 MW in Tunisia is 16.98 MW, while the potential capacity is estimated at 55.98 MW, indicating that approximately 30 per cent of the known potential has been developed.[10,11] There has been no change in either installed SHP capacity or estimated potential capacity since the *World Small Hydropower Development Report (WSHPDR) 2019* (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Tunisia (MW)**



Source: STEG,[10] *WSHPDR 2016*,[11] *WSHPDR 2013*,[12] *WSHPDR 2019*[13]

Note: Data for SHP up to 10 MW.

Tunisia has a great theoretical hydropower generation potential, which in the mid-1990s was estimated at 1,000 GWh/year, but the technically feasible generation potential is only approximately 250 GWh/year.[14] There is a total installed hydropower capacity of 67 MW in the country, of which 62 MW is connected to the national grid and approximately 5 MW is isolated. The oldest hydropower plant is located in Nebeur (Kef Governorate, northern Tunisia). Built in 1956, it is a reservoir-type plant with a capacity of 13.2 MW. In total, there are seven hydropower plants in Tunisia; of these, the hydropower plant of Sejnane with a capacity of 0.6 MW, is currently not operational (Table 1). Many of the existing hydropower plants were built during the period of French colonization and are predominantly located in the north-western region. The total annual electricity generation of these plants ranges between 50 and 160 GWh.[13]

Table 1. **List of Existing Hydropower Plants in Tunisia**

Hydropower plant	*Capacity (MW)*	*Operator*	*Launch year*
Sidi-Salem	36.00	-	-
Nebeur	13.20	-	-
Fernana	8.50+1.20	Neyrpic	1958-1962
El Aroussia	4.80	Franco Tosi	1956
Bouhertma	1.20+0.62	Alsthom	2003
Sejnane*	0.60	-	-
Kessab	0.66	-	1969
Total	**66.18**		

Source: STEG[10]

Note: *Out of operation.

The two large hydropower plants of Sidi Salem and Nebeur have capacities of 36 MW and 13.2 MW, respectively. Therefore, there are currently five SHP plants in Tunisia, at El Aroussia, Sejnane, Kessab, Fernana and Bouhertma. Their overall installed capacity stands at 16.98 MW.

The renewable energy (RE) strategy in Tunisia is focused on solar and wind power, which receive the support of the Government. Conversely, little interest is given to hydropower, either from the Government or private investors. This would explain the stagnation of hydropower installed capacity in comparison to other sources of RE in Tunisia.

However, in 2019, the National Company for the Exploitation and Distribution of Water (SONEDE) of Tunisia invited bids in separate tenders from qualified contractors to design, equip and build two micro-hydropower plants. These two projects are to be financed by the French Development Agency (AFD). They are located on the water supply network in Montfleury in the north-eastern Governorate of Tunis and at the upper reservoir of Lahirech in the north-western Governorate of Jendouba. The contracts will imply studies of the projects, supply and installation, testing and commissioning of electro-mechanical and electrical equipment, associated civil works, connection to the MV network of STEG, training of technical staff and after-sales service (including provision of spare parts).[15] The status of these two projects is currently unknown. Additional potential SHP sites identified in previous studies are displayed in Table 2.

Table 2. **List of Potential Small Hydropower Sites in Tunisia**

Location	*Potential capacity (MW)*
Barbara	3.00
Sidi Saad	1.75*
Bouhertma	1.20
Sejnane	1.00
Siliana	0.85
Bejaoua	0.75
Khanguet Zezia	0.65
Nebhana	0.50
Medjez el Bab	0.25
Total	**9.95**

Note: *Unconfirmed data.

RENEWABLE ENERGY POLICY

For more than three decades, Tunisia has pursued a proactive policy of energy management. The main axes of this policy are energy efficiency and the development of RE. Despite all the efforts made, the energy situation is characterized by a growing deficit in the energy balance, an increase in the energy bill and an increased dependence on fossil fuels.

In order to address the challenges facing the Tunisian energy system, the Government has committed to a policy of energy transition in the medium and long term. The important elements of this policy have included the creation of the Energy Transition Fund (FTE) in 2013 and the promulgation of the Law on Electricity Production from Renewable Energy Sources in 2015. In the field of energy management, the National Agency for Energy Management (ANME) is the main actor for the implementation of state policy. The ANME has a fundamental role in the energy transition process. The flagship initiatives carried out by the ANME have focused mainly on:

- Elaboration of strategic studies, especially in the areas of rational energy use, RE development and mitigation of greenhouse gas (GHG) emissions;
- Realization of sectoral studies on the energy mix of electricity production and on the Tunisian Solar Plan;
- Conducting specific studies on the financing of energy management initiatives, in particular the restructuring of the National Energy Management Fund (FNME) and the operationalization of the FTE;
- A study on the institutional reform of the ANME in order to enable the Agency to achieve its strategic objectives and to operate in an optimal and efficient manner.

The studies carried out by the ANME represent an essential tool for informing decision-makers on the prospects and challenges of the energy transition in Tunisia. These studies outline the strategic goals and the institutional, regulatory and financial measures necessary to achieve them. The main goals to achieve by 2030 are as follows:

- Reduce primary energy demand by 30 per cent compared to the trend scenario;
- Increase the share of RE in electricity production to 30 per cent;
- Reduce carbon intensity of the energy sector by 46 per cent compared to 2010.[16]

As part of the energy transition plan, Tunisia is striving to engage with international frameworks and agreements on implementing green and sustainable energy policies, including the Paris Agreement of 2015. In September 2015, Tunisia submitted its first National Determined Contribution (NDC), with the objective of reducing the carbon intensity of all sectors of the economy by 41 per cent in 2030 relative to 2010. Energy is placed at the heart of sectoral priorities in the field of emissions reduction, with a significant contribution of 75 per cent in the overall mitigation target of the Tunisian NDC. Energy efficiency and RE are the two main levers to achieve the objective assigned to the energy sector, which aims to reduce carbon intensity by 46 per cent in 2030 compared to the 2010 level. The capacity of the RE sector of Tunisia currently stands at 312 MW (6 per cent of all energy capacity), not including an additional 5 MW of hydropower not connected to the national grid. The aim for the share of RE in the electricity sector is to reach 30 per cent in 2030 (with an installed capacity of 3,815 MW). RE investments in Tunisia are mainly focused on the solar and wind power projects.[17]

The ANME has undertaken the necessary work to meet the requirements of a low-carbon energy transition in accordance with the recommendations of the Paris Agreement. In particular, the ANME has produced a database of GHG emissions of the energy sector over the period of 1980–2012 and an estimate for the period of 2013–2019. In addition, at the beginning of 2020, the ANME carried out a new inventory of GHG emissions in the energy sector covering the period of 2010–2019. The preparation of this inventory is based on the new methodology of the Intergovernmental Panel on Climate Change (IPCC). Furthermore, in 2020, an update of the NDC and elaboration of a National Low Carbon Strategy (NLCS) were initiated. These two elements represent the main instruments of the Tunisian climate policy and an opportunity to accelerate the energy transition and to address both the climate and the energy security issues. Their development defined medium and long-term goals for a changing energy landscape and low-carbon development to meet the energy, climate and socio-economic challenges for 2030 and 2050. Finally, the ANME has developed a monitoring methodology for the NDC in the energy sector, which should enable the assessment of progress towards the achievement of the mitigation target in the energy sector as defined by the NDC. In addition, it serves well to meet the transparency requirements of Article 13 of the Paris Agreement.[18]

In 2019 and within the framework of a partnership with the African Development Bank (AfDB), Tunisia made plans to create the "Fund Establishment and Fund Management Services for A Multi-Investor Equity/Quasi-equity Climate Impact Fund Financing Sustainable Energy Projects and Companies in Tunisia". In this regard, in 2019 the Fund of Deposits and Consignments (CDC) and the subsidiary of STEG, STEG-ER, launched a call for expressions of interest addressed at investment fund management companies and/or consortiums for the creation, development and management of an investment fund dedicated to the equity/quasi-equity financing of projects with a high environmental impact and oriented towards the energy transition of Tunisia.[19] This Fund aims to promote local currency financing in Tunisian dinars where most appropriate. The AfDB is collaborating with the CDC and STEG-ER in raising financing from a variety of international sources as part of a wider effort to catalyze investment in sustainable energy across the continent. The estimated duration of services is between July 2019 and December 2030. It is important to highlight that the CDC and STEG-ER retain the right to own up to 40 per cent of the fund management company.[20]

The main laws and decrees that regulate the RE sector in Tunisia are the following:

- Law No. 12 of 11 May 2015, which liberalizes the production and export of electricity from RE;
- Law of Investment No. 2016-71 of 30 September 2016 and Government decree No. 2017-389 of 9 March 2017, which provide financial and institutional incentives for investment in the RE sector;
- Law No. 2017-8 of 14 February 2017, which provides tax incentives for investments realized in the RE sector.[21]

The distribution and transportation of electricity remain exclusively the prerogative of STEG, which also sets the purchasing and transportation tariffs. Therefore, investors who self-produce their electricity using RE (and, therefore, are self-consumers) must first sign a contract for the sale of excess electricity produced from RE sources to STEG. Hence, STEG must buy back the surplus according to the established feed-in tariffs (FITs).

The FITs and transmission tariffs for electricity produced by self-consumers or for self-consumption were set by the decision of the Minister of Energy, Mines and Energy Transition of 27 May 2020 (Table 3).[22] The high-voltage (HV) electricity transmission tariff of 0.025 TND/kWh (0.009 USD/kWh; excluding VAT) is only applied for self-consumer organizations benefiting from the right to sell electricity produced from RE and whose production units are connected to the HV network.[23] The tariffs set by this decision apply to the electricity produced from 1 June 2020 on the entire territory of the country.[22]

Table 3. **FITs on Surplus Renewable Energy Electricity Sold by Self-Consumers in Tunisia**

Period	*Price (TND/kWh (USD/kWh))**
Day	0.073 (0.026)

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

SHP implementation in Tunisia is hindered by several barriers:

- Technical barriers such as: limited access to appropriate technologies in the mini-, micro- and pico-hydropower categories, which pose specific technical challenges; and limited specialization to undertake feasibility studies;
- Energy/electricity sector barriers: mainly the high competition with other RE technologies as well as the maturation of solar and wind power technologies;
- Political barriers: there is limited commitment on the part of the Government to encourage and promote SHP technologies;
- Financial barriers: there is limited participation from the private sector, in part due to a lack of stable funding for SHP and in part due to better investment opportunities with other RE sources.[13]

Recently, Tunisia has experienced a marked increase in rainfall, especially between the years 2018 and 2019. This in turn has led to increased river discharge and a considerable improvement in dam reservoir levels. As a result, electricity generation by the Tunisian hydropower sector as a whole rose to almost 66 GWh in 2019, a 299.4 per cent increase over the previous year. If these weather patterns continue, SHP could become a more promising source of RE for Tunisia in the future.

1.4. Southern Africa

Countries: Botswana, Eswatini, Lesotho, Namibia, South Africa

INTRODUCTION TO THE REGION

South Africa is the largest economy in the region by a wide margin, with a robust electricity sector. Thermal power, mainly from coal-fired power plants, accounted for approximately 82 per cent of installed capacity and 86 per cent of generation in 2021. The country also operates the region's only nuclear power plant with an installed capacity of 1,940 MW. The country has some of the highest rates of electricity access in the region, but rural areas still lag behind the rest of the country. Imports of electricity from South Africa contribute a significant share of the electricity supply of all other countries in the region, with Lesotho importing over 50 per cent and Eswatini nearly 80 per cent of their electricity from South Africa. Regional electricity generation is dominated by state-owned companies. The public utility of South Africa ESKOM, the single-largest regional power producer, operates over 89 per cent of the generating capacity of South Africa while the rest is operated by independent power producers (IPPs) and municipalities.

Hydropower development in the region displays some notable characteristics tied to the regional dependence on electricity imports from South Africa. In South Africa itself, hydropower plays a supplementary role, accounting for only 6 per cent of capacity and 3 per cent of generation as of 2021. At the same time, hydropower accounts for the majority of all domestic electricity generation in Namibia and Eswatini and over 99 per cent in Lesotho, with Namibia additionally investing heavily in solar power. Thus, these three countries have adopted a strategy of sourcing their domestic electricity generation from renewable energy while relying on imported electricity from thermal power for the bulk of their energy needs. Botswana is likewise dependent on electricity imports to a significant extent, but has no domestic hydropower capacity due to climactic and topographical factors and has instead opted to source its domestic generation from coal-fired and diesel-fired power plants.

An overview of the electricity sectors of the countries in the Southern Africa region is provided in Table 1.

Table 1. **Overview of Southern Africa**

Country	*Total population (million people)*	*Electricity access, total (%)*	*Electricity access, rural (%)*	*Total installed capacity (MW)*	*Electricity generation (GWh/year)*	*Hydropower installed capacity (MW)*	*Hydropower generation (GWh/year)*
Botswana	2	62	62	893	3,332	0	0
Eswatini	1	77	70	109	293	69	227
Lesotho	2	45	32	77	389	76	392

Note: Data in the table are based on data contained in individual country chapters of the *WSHPDR 2022*; years may vary.

REGIONAL SMALL HYDROPOWER OVERVIEW

The definition of small hydropower (SHP) in Southern Africa varies across countries. Botswana, Eswatini and Namibia do not have a local definition of SHP, in Lesotho SHP is defined as hydropower plants of up to 10 MW, while in South Africa the up to 40 MW definition is used alongside the up to 10 MW definition. A comparison of installed and potential capacities in the region is provided in Table 2.

Table 2. **Small Hydropower Capacities by Country in Southern Africa (MW)**

Country	*Local SHP definition*	*Installed capacity (local def.)*	*Potential capacity (local def.)*	*Installed capacity (≤10 MW)*	*Potential capacity (≤10 MW)*
Botswana	N/A	0.0	N/A	0.0	1.0
Eswatini	N/A	8.2	16.2	8.2	16.2
Lesotho	Up to 10 MW	3.8	38.2	3.8	38.2
Namibia	N/A	0.1	120.0	0.1	120.0
South Africa	Up to 40 MW	N/A	N/A	42.0	247.0
Total	-	-	-	**54.1**	**422.4**

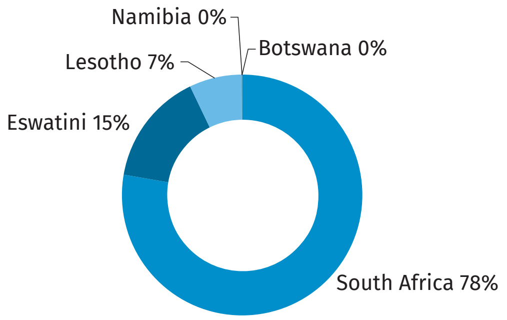
Source: *WSHPDR 2022*[1]

The installed capacity of SHP up to 10 MW in Southern Africa is 54.1 MW, while the estimated potential capacity is 422.4 MW. Relative to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed capacity has increased by 8 per cent, while the estimated potential capacity has remained the same.

The role of SHP in the Southern Africa region varies from country to country and is heavily influenced by economic and environmental factors. Botswana and Namibia both have little to no existing SHP capacity due to low population densities and semi-arid conditions predominating across much of their territory. South Africa operates the majority of the region's installed SHP capacity, but the country's SHP capacity is low relative to that of large hydropower and other energy sources and plays a minor role in the domestic electricity supply. SHP provides a substantial share of the total installed electricity capacities of Eswatini and Lesotho, with both countries possessing significant hydropower resources, but the role of SHP in these two countries should not be overstated due to their heavy reliance on electricity imports. The overwhelming share of SHP potential in the region (87 per cent) is represented by South Africa and Namibia. Significant potential may additionally exist in Botswana but has not been confirmed in detailed studies.

The national share of regional installed SHP capacity by country is displayed in Figure 1, while the share of total national SHP potential utilized by the countries in the region is displayed in Figure 2.

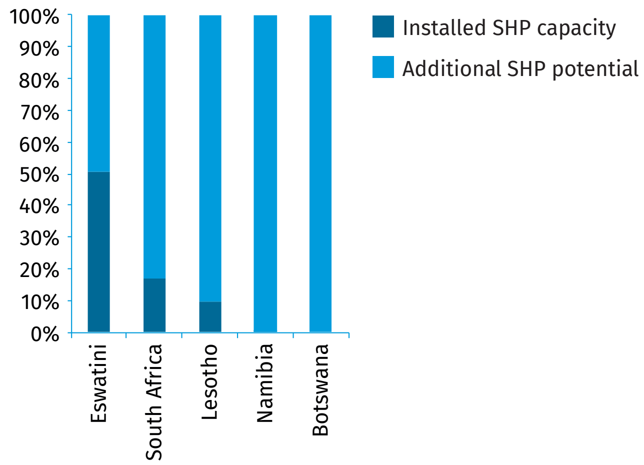
Figure 1. **Share of Regional Installed Capacity of Small Hydropower up to 10 MW by Country in Southern Africa (%)**



Source: *WSHPDR 2022*[1]

Note: Botswana not included due to absence of installed SHP capacity.

Figure 2. **Utilized Small Hydropower Potential up to 10 MW by Country in Southern Africa (%)**



Source: *WSHPDR 2022*[1]

There are no SHP plants in **Botswana**. Hydropower potential in the country is low due to prevailing topographical features and climatic conditions. One study has identified an SHP potential of approximately 1 MW in the northern part of the country, while a more recent, continent-scale study suggested a significantly higher theoretical potential of 1,289 MW for SHP up to 10 MW. However, this latter figure is likely an overestimate and further detailed studies are necessary that account for current climatic conditions and economic constraints.

The installed capacity of SHP up to 10 MW in **Eswatini** is 8.2 MW from four SHP plants, of which one has been decommissioned but is still technically operational. Most of the existing plants were constructed between 1950 and 1990 and no new SHP plants have been commissioned in recent years, with hydropower development focusing on larger projects. Undeveloped SHP potential was estimated at 8 MW in 2001, with an array of potential micro-, mini- and small hydropower sites identified in subsequent studies. The total SHP potential of the country following the up to 10 MW definition, including existing capacities, is thus estimated at 16.2 MW, indicating that approximately 51 per cent has been developed.

Lesotho has an installed SHP capacity of 3.8 MW from five SHP plants, of which only two plants with a total capacity of 2.2 MW are operational. The potential capacity of the country, including existing plants, is estimated at 38.2 MW, indicating that 10 per cent of SHP potential up to 10 MW has been developed. No new SHP plants have been built in the last two decades, but plans for the rehabilitation of currently non-operational plants are in place.

Namibia has a single SHP plant with an installed capacity of 0.05 MW. The role of SHP in the country's electricity sector is negligible. Namibia has several perennial rivers, one of which hosts a large hydropower plant, but smaller streams appropriate for SHP development are rare as the country is one of the driest and water-stressed in the region and globally. Plans have been proposed to develop 13 SHP plants on the Orange River with a total capacity of 120 MW.

In **South Africa**, the installed capacity of SHP up to 10 MW stood at 42 MW as of 2021, while potential capacity was estimated at 247 MW, indicating that 17 per cent of the known potential is currently utilized. A large number of SHP plants exists throughout the country, but the operational capacity has fluctuated considerably over the past 60–70 years as old plants have been decommissioned and new ones constructed in their place. Many operational plants are located on private land and are not connected to any private grid, supplying power for self-consumption to commercial entities such as mines and resorts. The SHP sector in the country has seen an increase in activity starting with 2009 following decades of neglect, in part due to the promotion of renewable energy sources under the REIPPP programme implemented by the Government. Several new SHP plants have been constructed in recent years.

Changes in the installed SHP capacities of countries in the Southern Africa region compared to the previous editions of the *World Small Hydropower Development Report (WSHPDR)* are displayed in Figure 3.

Figure 3. **Change in Installed Capacity of Small Hydropower up to 10 MW from *WSHPDR 2013* to *WSHPDR 2022* by Country in Southern Africa (MW)**

Climate Change and Small Hydropower

In South Africa, the Western Cape region is expected to see a 13 per cent decline in the average annual runoff, while the eastern coast will experience an increased risk of flooding. Countries in the Zambezi River basin, which includes Namibia and Botswana, have already experienced climate change, especially rainfall variability. The projected continuous rise in evaporation and evapotranspiration due to the increased temperatures could spur higher water stress in the region. However, the impacts on runoff are yet uncertain.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

In **Botswana**, SHP development is hindered by existing climatic and topographic conditions, which include the flat nature of the terrain with few perennial rivers, as well as by lack of detailed studies of SHP potential.

Eswatini has considerable hydropower resources including untapped SHP potential, but development of SHP in the country is hindered by limited private sector investment, reliability issues with the national electricity grid, and lack of detailed data on sites in need of refurbishment. However, there is renewed interest in SHP development in the country, particularly in the rehabilitation of old SHP plants. This interest is driven in part by rising electricity prices and has resulted in several recent studies assessing undeveloped SHP potential.

The SHP potential of **Lesotho** is likewise significant, relative to the size of the country and existing electricity demand. However, a variety of factors have prevented this potential from being realized, including lack of government planning and local technical capacity for SHP development, difficulty of access to potential sites and small size of the electricity market in the country. Additionally, existing hydropower resources are increasingly stressed by climate change.

Namibia has significant undeveloped SHP potential, but economic factors and a lack of a legislative framework for SHP development have hindered its realization. An additional barrier is that most significant hydropower resources are shared with neighbouring countries, while inland hydropower resources are rare and the country's water resources in general are stressed by variability induced by climate change. At the same time, government policy is broadly supportive of renewable energy development and provides incentives in the form of renewable energy funds and feed-in tariffs.

The main barriers to SHP development in **South Africa** are the lengthy and complicated licensing procedures as well as a lack of interest in financing SHP projects on the part of local banks. Nonetheless, SHP is considered an attractive option for electricity producers in the country alongside other renewable energy sources due to the high relative cost of power generation from fossil fuels. Additional incentivization of SHP is not required and a well-established bidding process for RES projects (REIPPP) has been in place for over a decade. Considerable undeveloped SHP potential remains in the country, particularly on existing water supply infrastructure, which South Africa has in abundance.

Botswana

Mareledi Gina Maswabi, Department of Energy

KEY FACTS

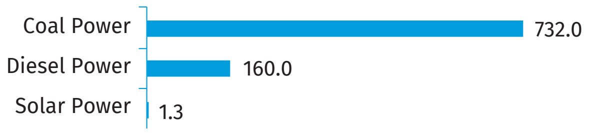
Population	2,351,625 (2020)[1]
Area	581,730 km² [2]
Topography	Botswana is generally flat with a mean altitude of 1,000 metres. A large plateau of approximately 1,200 metres in height divides the country into two distinct topographical regions. The eastern region is hilly, with bushland and grasslands, whereas to the west lies the Okavango Swamps and the Kalahari Desert.[3]
Climate	Botswana has a semi-arid and subtropical climate with both wet and dry conditions. The semi-arid condition makes the climate highly dynamic with variable and sometimes extreme weather. During the dry season, which lasts from April to October in the south and up to November in the northern part, day temperatures can rise to 38 °C and higher, reaching 44 °C on rare occasions in some areas. The winters are dry and clear-skied. Since there is no cloud cover, the air is warmer during the daytime and colder at night. Early mornings have temperature averages 4 °C.[4]
Climate Change	Botswana is vulnerable to climate change, particularly to increasing temperatures and fluctuating rain patterns. Studies show decreased rainfall throughout the country, associated with decreases in the number of rainy days.[5]
Rain Pattern	In Botswana, rains are experienced during summer, peaking in January and February. Rainfall appears to be highly regional, unpredictable and sporadic. The south-west experiences the least average annual rainfall of less than 220 mm, while the north-eastern region receives the highest rainfall averaging 500 mm. The mean annual rainfall ranges from a maximum of over 650 mm in the extreme north-east of the Chobe District to a low of less than 250 mm in the extreme south-west of the Kgalagadi District. There is little to no rain during winter and humidity is low, typically 20–40 per cent. Annual rainfall trends indicate a general decline.[4,6]
Hydrology	Due to its low topography, the country's water storage capacity is one of the lowest in the region. Water sources consist mainly of surface water from rivers of varying sizes, pans and dams, and deep water in aquifers, some of which are non-rechargeable and fossil in nature.[7] The Chobe River in the north, the Limpopo in the south-east and the Okavango in the north-west are the only year-round sources of surface water. These perennial rivers are shared with neighbouring countries. The shared river basins include Okavango, Zambezi, Orange-Senqu and Shashe-Limpopo.[8] The total dam-water capacity is currently estimated at 800 mm³, while the underground capacity (developed resources) is at 131,290 m³/day. The lack of further economical dam sites in Botswana represents a cap in water storage capacity. Waste water makes up 16 per cent of all water supplies, of which just 20 per cent is reused.

ELECTRICITY SECTOR OVERVIEW

Botswana is endowed with abundant coal and solar energy resources. Coal reserves are estimated at approximately 212 billion tons and approximately 2.7 trillion cubic metres of coal-bed methane (CBM) have also been recorded.[9] Besides coal and CBM, there are no other proven reserves of possible fossil fuel resources such as natural gas or oil. There is an abundance of solar power potential countrywide as well as a significant potential from wind power and bioenergy, which is underdeveloped. Countrywide average direct normal irradiance (DNI) solar potential is 6.83 kWh/m² per day with the highest annual sums in the south-western parts of the country.[10] The lowest values are in the extreme eastern parts; however, these remain on a par with the highest resource areas of Europe. Annual energy production from wind is estimated at above 4.5 GWh per year. The theoretical potential of biomass is estimated at 32 million GJ per year, with the use of livestock residues (manure) offering the highest practical opportunity for energy production. Municipal solid waste can also contribute significantly towards energy generation at the city level.

Electricity consumption in Botswana stood at approximately 4,505 GWh per year in 2020 and is expected to reach 8,637 GWh per year by 2040 driven by economic growth.[11] Demand stands at 600 MW and installed capacity stands at 893.3 MW, with 732 MW coming from coal (Morupule A and B power plants), 160 MW from diesel (Orapa and Matshelagabedi plants) and 1.3 MW from solar power (Figure 1).[11,13] There is still a significant amount of power imported from neighbouring countries to augment local supply since the coal-fired plants are not generating to maximum capacity. Morupule A, with a total capacity of 132 MW and a lifetime ending in 2026, is expected to supply 1,020 GWh when fully operational, but on average only delivers approximately 843 GWh of electricity per year.[12] Morupule B, with an installed capacity of 600 MW (4 units of 150 MW) is under remedial works and has not worked to its full capacity since its commissioning in 2014. To date, Morupule B provides approximately 2,299.5 GWh per year and is expected to operate fully by the year 2023. The Orapa (90 MW) and Matshelagabedi (70 MW) emergency diesel-peaking plants were commissioned in 2010 and 2011, respectively. They were intended to mitigate the possible risk of supply shortfall during the Morupule B power plant remedial works period.

Figure 1. **Installed Electricity Capacity by Source in Botswana in 2020 (MW)**



Source: BCP[13]

At the moment, the share of renewable energy in electricity generation is very insignificant and precise figures on solar power generation in the country are not reported on systematically. In 2019, total electricity generation stood at 3,332 GWh, of which solar power accounted for less than 0.2 per cent (Figure 2).

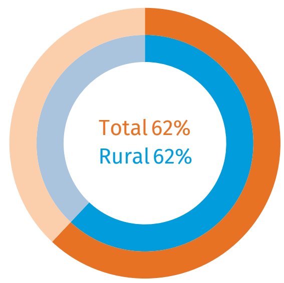
Figure 2. **Annual Electricity Generation by Source in Botswana in 2019 (GWh)**

Source: IRENA[14]

The overall national electricity access rate is 62 per cent, with 61.56 per cent in urban areas and 61.60 per cent in rural areas (Figure 3).[9] The Government has committed to an ambitious target of achieving 100 per cent national electricity access by 2030.[15] To meet this target, it is expected that 30 per cent of the rural population's access will be provided by solar home systems and a further 7 per cent of the rural population will be served by mini-grids.[16]

Having depended on imports from neighbouring countries for a long time, Botswana is now striving for self-sufficiency in electricity. Since 2016, most of the country's electricity needs are met by local generation through a state-owned entity, namely, Botswana Power Corporation (BPC), mainly from the two coal power plants (Morupule A and Morupule B), augmented by the two diesel-operated peaking plants (Matshelagabedi and Orapa). BPC is responsible for the generation, transmission and distribution of electricity and currently holds the sole rights to transmission and distribution. BPC is also involved in the promotion of the involvement of individual power producers (IPPs) in the field of renewable energy.

Figure 3. **Electrification Rate in Botswana in 2021 (%)**



Source: Ministry of Mineral Resources, Green Technology and Energy Security9

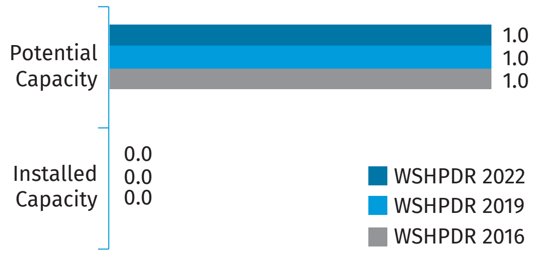
The Electricity Supply (Amendment) Act of 2007 allows for IPPs to partake in generation even though, to date, there is no IPPs playing a role in the electricity sector of Botswana.[17] In accordance with the Electricity Supply Act and the Botswana Power Corporation Act, Botswana Energy Regulatory Authority (BERA) regulates the production, transmission, distribution and selling of electricity through the BERA Act of 2016.[18] An Integrated Resource Plan (IRP) of 2020 outlines the country's power build programme for a period of 40 years, taking into account generation from various energy sources.[19]

The Southern African Development Community (SADC) has developed a competitive electricity market for the region since 2004. Regional electricity prices are analyzed as part of the Southern African Power Pool (SAPP) Plan, which seeks to identify a core set of generation and transmission investments of regional significance that can provide adequate electricity supply and support enhanced integration and power trade in the region. In line with this, Botswana aims to diversify and increase economic development by securing competitive, cost-reflective and sustainable electricity prices. As at June 2020, the price of electricity in Botswana was 0.109 USD/kWh and 0.130 USD/kWh for households and businesses, respectively.[20]

SMALL HYDROPOWER SECTOR OVERVIEW

Due to its aridity, Botswana does not have any hydropower plants and there is no advocacy for hydropower development in the existing energy policies and plans. The potential SHP capacity of the country is estimated at 1 MW.[21] No changes in the small hydropower (SHP) sector in the country have taken place since the *World Small Hydropower Development Report (WSHPDR) 2019* (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2016/2019/2022 in Botswana (MW)**



Source: Jonker Klunne,[21] Korkovelos et al.,[22] *WSHPDR 2016*,[23] *WSHPDR 2019*[24]

It has been reported that there is potential for a 1 MW site in the northern part of the country.[21] A more recent geospatial study showed a significantly higher theoretical potential: 70.4 MW for mini-hydropower (0.1–1 MW) and 1,218.6 MW for SHP (1.01–10 MW).[22] This study was undertaken at a continental scale and likely overestimates the amount of water resources available under the current climatic conditions. A thorough, more focused research on hydropower potential in Botswana is needed and would help inform policy making around the development of hydropower in the country.

The current backup power plants in Botswana are relying on diesel fuel and replacing these with cleaner options such as hydropower would assist the country meet its climate and sustainable development goals while ensuring reliable electricity supply. However, lack of hydrological resources in the country is a key barrier and disincentive.

RENEWABLE ENERGY POLICY

The Ministry of Mineral Resources, Green Technology and Energy Security, through the Department of Energy is the coordinator of all development activities in the sector. The Government of Botswana recognizes the importance of limiting activities that could harm the environment as presented in Vision 2036 and the Eleventh National Development Plan (2017–2023).[25,26] The Nationally Determined Contributions (NDC) of Botswana presents a commitment of 15 per cent greenhouse gas emissions reduction by 2030, using 2010 as a baseline.[27] The NDC recognizes the energy sector as the target as it is the largest contributor to the country's total emissions.

Considering the abundance of solar power, renewable energy is prioritized in the energy sector plans. The National Energy Policy of 2021 advocates for renewable energy development through private sector participation in the electricity sector, including IPPs, to expand generation capacity.[9] According to the Renewable Energy Strategy of Botswana, the development of large-scale grid-connected renewable energy may be expected to contribute in the order of 20 per cent of total electricity consumption in Botswana by 2030, a target that would likely be met almost entirely via large-scale solar generation.[10]

The existing policies are silent on energy generation from hydropower plants considering the scarcity of the water resource in the country. Despite the potential being there, it is unlikely that any hydropower projects will be developed in Botswana in the near future.

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

In 2012, Botswana developed a renewable energy feed-in tariff (FIT), which, however, was never effected due to the high estimated subsidy costs. At the moment of writing of this chapter, the FIT was undergoing review. Guidelines have been developed for rooftop solar power and biofuels, but there is no guideline in place for wind power or hydropower generation.[28]

Effective implementation of renewable energy will require public-private partnerships and this creates room for local and foreign investment. There is currently no articulated framework for public-private partnerships (PPPs) in the power sector, nor are there any standard power purchase agreements (PPAs) in place. Development of such critical policy implementation tools is vital especially given that the envisaged projects stipulated in the country's IRP have been endorsed by the Cabinet for implementation through IPPs.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Regional changes in rainfall and water availability, protracted drought events, significant variation in temperature regimes and more frequent and severe weather events are the climate change impacts that can affect the hydropower sector. These effects have an impact on the future sustainability of any SHP development, which could discourage potential investment.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The key barriers to SHP development in the country include:

- No existing hydropower plants in the country;
- Lack of plans towards hydropower development;
- Flat topography;
- Limited water resources.

At the same time, networked micro-hydropower could still be a possibility despite the existing natural limitations. New studies could clarify the availability of SHP potential.

Eswatini

Wim Jonker Klunne, Hydro4Africa

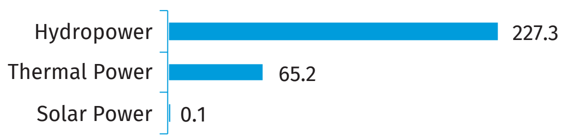
KEY FACTS

Population	1,148,130 (2019)[1]
Area	17,360 km^2[2]
Topography	The Kingdom of Eswatini is a landlocked country in Southern Africa, bordered to the north, south and west by South Africa and to the east by Mozambique. Eswatini is a small country of no more than 200 km north to south and 130 km east to west. The western half is mountainous, descending to the Lowveld region to the east. The eastern border with Mozambique and South Africa is dominated by the escarpment of the Lebombo Mountains. The lowest point is the Great Usutu River, at 21 metres above sea level, and the highest is Emlembe Mountain, at 1,862 metres.[3]
Climate	The climate is temperate in the west, but temperatures can reach 40 °C in the eastern Lowveld region during the summer months, between October and March. In the capital city, Mbabane, the average temperature is 20 °C in January and 12 °C in July.[3]
Climate Change	Despite not emitting large quantities of greenhouse gas emissions, Eswatini is facing severe climate change impacts. Variable precipitation patterns, droughts, desertification, higher temperatures and increased storm intensities have already affected the country's population and key economic sectors. As a developing, lower-middle income country, with 69 per cent of the population living below the poverty line, Eswatini has little capacity to cope with these impacts.[4]
Rainfall Pattern	Rainfall occurs mainly in the summer months, between October and March. Average annual rainfall may reach 2,000 mm in the western Highveld region, but decreases towards the east with the Lowveld region averaging between 500 mm and 900 mm.[3]
Hydrology	Major perennial rivers, which have their sources in South Africa, flow through the country to the Indian Ocean. They are the Lomati, Komati, Umbuluzi and Usutu. The Usutu has the largest catchment in the country, with three main tributaries: the Usushwana, Ngwempisi and Mkhondvo.[5]

ELECTRICITY SECTOR OVERVIEW

The Eswatini electricity grid is supplied by the Eswatini Electricity Company (EEC) through four hydropower plants (Ezulwini of 20.2 MW, Maguga of 19.5 MW, Edwaleni of 15.0 MW and Maguduza of 5.6 MW), Ubombo Sugar Limited (40.5 MW of biomass supplemented by coal), the Wundersight's Buckswood 100 kW solar photovoltaic (PV) plant and 8.2 MW of small hydropower (SHP) capacity. The country's total installed capacity as of 2020 was 109.1 MW (Figure 1). In addition, there are several private self-generating plants owned by the industrial sector. In 2021, the new 10 MW Lavumisa solar PV plant owned by the EEC began commercial operation.[6,7]

Figure 1. **Installed Electricity Capacity by Source in Eswatini in 2020 (MW)**

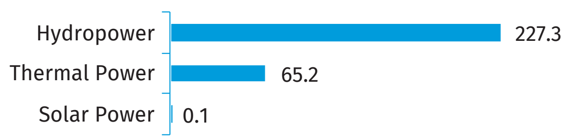


Source: EEC[6]

Note: Thermal power includes generation from coal and biomass; data do not include privately owned self-generation.

The local generation is augmented by imports through the Southern African Power Pool (SAPP), with South African utility ESKOM as the major source of electricity. The total electricity generated in the country reached 292.6 GWh at the end of the 2019/2020 financial year (Figure 2). Eswatini is still highly reliant on electricity imports, with approximately 1,028 GWh of electricity imported in 2020.[6]

Figure 2. **Annual Electricity Generation by Source in Eswatini in 2020 (GWh)**



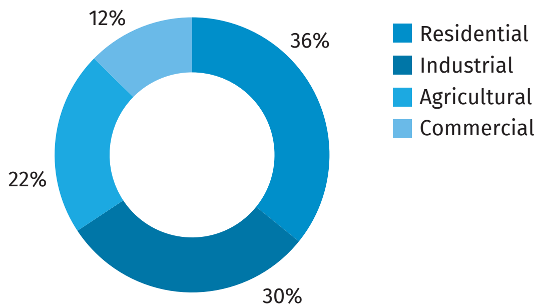
Source: EEC[6]

Note: Thermal power includes generation from coal and biomass; data do not include privately owned self-generation.

The four hydropower plants of EEC have a total installed capacity of 60.3 MW and contributed 17.2 per cent to the country's total electricity supply (including imports) in the financial year 2019/2020.[6] Total hydropower generation in 2019/2020 amounted to 227.3 GWh, compared to 266.1 GWh in the previous financial year. The EEC hydropower plants are located in the Usuthu River catchment basin (Ezulwini, Edwaleni and Maguduza plants) and in the Komati basin (Maguga plant).[6]

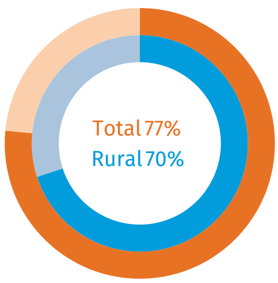
In 2020, the residential and industrial sectors dominated national electricity consumption, with 36 and 30 per cent of the total, respectively (Figure 3).[6] The overall electrification rate is estimated at approximately 77 per cent, with approximately 97 per cent of the urban areas and 70 per cent of the rural areas electrified (Figure 4).[8] Biomass, especially wood fuel, constitutes approximately 90 per cent of the total energy consumed and is still dominant in cooking and heating in rural areas. Biomass is not only the major fuel in households, but also the major source of electricity self-generation in the sugar, pulp and sawmill industries.

Figure 3. **Electricity Consumption by Sector in Eswatini in 2020 (%)**



Source: EEC[6]

Figure 4. **Electrification Rates in Eswatini in 2020 (%)**



Source: World Bank[8]

As of 1 April 2020, the consumer tariffs ranged from 1.0887 SZL/kWh (0.077 USD/kWh) to 2.4144 SZL/kWh (0.17 USD/kWh) (Table 1) for non-time of use (TOU) customers, while the price for TOU customers can be as high as approximately 5 SZL/kWh (0.35 USD).[9]

Table 1. **Consumer Tariffs in Eswatini in 2020/21**

Tariff type	*Facility charge per month (SZL (USD))*	*Energy charge per kWh (SZL (USD))*
Life line		1.089 (0.08)
Domestic		1.806 (0.13)
General purpose	208.46 (14.75)	2.414 (0.17)
Small commercial prepayment	208.46 (14.75)	2.414 (0.17)

Source: EEC[10]

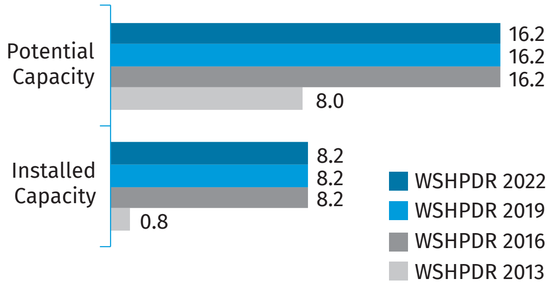
EEC was established in 2007 as the Swaziland Electricity Company (SEC) by the Swaziland Electricity Company Act of 2007.[11] It currently operates as a monopoly with regards to the import, distribution and supply of electricity via the national power grid and owns the majority of the country's power plants. There are also a number of private power plants. A substantial amount (almost 25 per cent) of the energy used in the country is supplied by self-generators. A reform of the energy sector has been undertaken to reduce the monopoly of the utility (change from a board to a company in 2007), establish a regulatory body and to ensure proper oversight over the state company as a corporate entity.[12] The following powers and functions have been given to the Eswatini Energy Regulatory Authority (ESERA; formerly the Swaziland Energy Regulatory Authority, SERA):

- Receive and process applications for the licences and modify/vary the licences;
- Approve tariffs, prices, charges, terms and conditions of operating a licence;
- Monitor the performance and efficiency of licensed operators.

SMALL HYDROPOWER SECTOR OVERVIEW

There is no official definition for SHP in Eswatini, therefore, this chapter assumes a definition of plants less than 10 MW. The installed capacity of SHP in the country is currently 8.205 MW, including the decommissioned but still technically operational 0.5 MW plant at Mbabane.[13] Additional potential capacity is estimated to be at least 8 MW, indicating that more than 50 per cent of the available potential has been developed so far.[14] In comparison to data from the *World Small Hydropower Development Report (WSHPDR) 2019*, both the installed and potential capacities have remained the same (Figure 5).

Figure 5. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Eswatini (MW)**



Source: Jonker Klunne,[13] Knight Piesold Consulting,[14] WSH*PDR 2013*,[15] *WSHPDR 2016*,[16] *WSHPDR 2019*[17]

Currently, only six hydropower plants are operational in the country, three of which have capacities of less than 10 MW (Table 2).[13] EEC operates the grid connected to the Ezulwini (20.0 MW), Maguga (19.5 MW) Edwaleni (15.0 MW) and Maguduza (5.6 MW) plants. The Mbabane plant of 500 kW was decommissioned by EEC in December 2010 as it was no longer able to operate profitably.[18] In 2018, the African Development Bank submitted a concept note to the Green Climate Fund, which includes a proposed rehabilitation of the Mbabane plant at an estimated cost of USD 7 million. At the moment the AfDB Is trying to mobilize co-funding for the project before it can be considered for approval.[19] Two private SHP plants are also in operation: the 800 kW plant of Swaziland Plantations and the 1.305 MW plant of Ubumbo Sugar in Big Bend.[13]

Table 2. **List of Small Hydropower Plants in Eswatini**

Name	*Location*	*Capacity (MW)*	*Head (m)*	*Plant type*	*Operator*	*Launch year*
Ezulwini	Ezulwini valley	20.0	–	Pelton, storage	EEC	1985
Maguga	Hhohho	19.5	50 –90	Francis, storage	EEC	2006
Edwaleni	Manzini	15.0	141	Dam with run-of-river	EEC	1969
Maguduza	Manzini	5.6	–	Dam with run-of-river	EEC	1969
Ubumbu Sugar	Big Bend	1.3	28	Cross-flow, run of river	Ubumbu Sugar	1986
Swaziland Plantations	Pigg's Peak	0.8	76	Francis, storage	Swaziland Plantations	1952
Mbabane*	Mbabane	0.5	–	–	EEC	1954

Source: Jonker Klunne[13]

Note: *decommissioned.

Both the Edwaleni and Maguduza plants feed from the Greater and the Little Usutu Rivers. In the mid to late 1980s EEC encountered serious problems with siltation in the canal and pondage system to such an extent that an island had formed. This not only reduced the plants' capacity to provide peak power but also caused severe wear on the turbines.[20] Currently, the plants are free of siltation problems. The Edwaleni plant also comprises three sets of diesel generation facilities (2 x 4.5 MW + 1 x 0.5 MW), however these are seldom utilized by EEC because of the high costs involved.

The hydropower plant of Swaziland Plantations was initially commissioned in 1952 and was built to provide for the power needs of the town of Piggs Peak. The water is taken from the river and stored in a 35-metre-high dam, before being fed into a 1.75 metre in diameter, 300-metre-long tunnel, which is then connected to the penstock. The head is 76.2 metres. The two 400 kW Francis turbines are designed to take a water flow of 0.8 m^3/s and have an efficiency of approximately 85 per cent (when running at full capacity). They are each connected to a three-phase 415 kVA alternator. The alternators feed into an 800 kVA transformer, which is synchronized to the EEC system and feeds a 16-kilometre-long, 11 kV line direct to the sawmill. During summer, when there is an abundance of water, the plant can satisfy approximately 90 per cent of the company's power needs.[21] Current operations are highly dependent on water availability, with approximately a quarter of summer production levels possible in the winter, dry season.

The 1.305 MW hydropower plant on the Great Usuthu River was commissioned in 1986 and consists of two 728 kW Ossberger turbines. The plant provides power to the sugar processing facilities in Big Bend.[13]

Feasibility studies are currently ongoing for the Ngwempisi cascading project, which is expected to have a total installed capacity of 120 MW over three different sites. Furthermore, at least one owner of an old defunct 50 kW hydropower plant just outside Mbabane is considering rehabilitation.[22] The success of the existing Maguga hydropower plant has also encouraged EEC to consider exploring the potential of adding extra generating equipment on the existing plant as well as constructing another power plant approximately 7 kilometres downstream of the current one. An engineering consulting firm has been engaged to carry out a full feasibility study, including a further investigation of the potential to develop a 10 MW site down the Maguga plant, which will utilize the existing Maguga dam. The intention is to take advantage of the remaining capacity below 35 per cent of the Maguga dam level at the downstream hydropower plant.[6] Expanding the Maguga plant will increase the local generation capacity and decrease the dependence on imported power. The extra generation units will also ensure that some of the excess water, which normally spills during the rainy seasons, is used to generate power. In addition, T-Colle Investments of Mbabane is looking to build an SZL 5 million (USD 575,000) hydropower plant with a capacity of 360 kW on a canal in the central Manzini region. The firm will charge EEC SZL 0.70 (USD 0.081) per kWh for the first three years of production (Table 3).[23]

Table 3. **List of Planned Small Hydropower Projects in Eswatini**

Name	*Location*	*Capacity (MW)*	*Plant type*	*Development stage*
Maguga extension	Maguga	10.00	–	Feasibility study
Maguga downstream	Maguga	10.00	Run-of-river	Feasibility study
Lubovane		0.85	–	Feasibility study
Dwaleni's Ferreira Canal	Manzini	0.36	Run-of-river	Feasibility study
Mbabane	Mbabane	0.05	–	Feasibility study

Source: Jonker Klunne[13]

A joint 1987 United Nations Development Programme (UNDP) and Energy Sector Management Assistance Programme (ESMAP) study on the energy sector in Eswatini identified a total of approximately 1 MW of non-utility hydropower generation capacity.[21] The latest full study on hydropower potential in Eswatini however was carried out by Knight Piesold Consulting in 2001. The study showed that there is a number of potential micro- (<0.1 MW), mini- (0.1–2.0 MW) and small (2–10 MW) hydropower sites with an available potential of approximately 8 MW.[24] As part of its objective to expand the hydropower sector, the Ministry of Natural Resources and Energy (MNRE) has, based on the findings of Knight Piesold Consulting, built a database of potential sites. Initially, 35 candidate sites were identified, ranging from 32 kW to 1.5 MW. This was further reduced to 26, based on the potential for electricity generation. Four have been identified as viable projects and are being promoted by MNRE: Lusushwana River (300 kW), Mpuluzi River (155 kW), Usutu River (490 kW) and Mbuluzi River (120 kW minimum) (Table 4).[25]

Several studies have been undertaken to estimate the total hydropower potential of Eswatini. In 1970, the UNDP financed a study by Engineering and Power Development Consultants, which identified 21 potential sites.[20] Based on existing information, the Environmental Centre for Swaziland (now Eswatini Environment Authority) estimated a gross theoretical potential of 440 MW and technically exploitable potential of 110 MW, of which 61 MW is economically exploitable.[25]

Table 4. **List of Small Hydropower Sites Available for DDevelopment in Eswatini as of 2021**

Name	*Potential capacity (MW)*	*Type of site (new/ refurbishment)*
Lusushwana River	0.300	New
Mpuluzi River	0.155	New
Usutu River	0.490	New
Mbuluzi River	0.120	New

Source: IRENA[26]

RENEWABLE ENERGY POLICY

In 2007, MNRE formulated a strategic framework and action plan with the aim to:

- Establish a centre for demonstration and education on renewable and sustainable energy;
- Encourage and enhance, where applicable, topics on renewable energy and energy in general in educational and training curricula;
- Maximize the use of renewable energy technologies wherever they are viable;
- Promote greater understanding and awareness of renewable energy resources and associated technologies;
- Develop and maintain accurate data on renewable energy resources and make them available to all, in order to make informed policy decisions regarding the sustainable energy use and supply;
- Develop woodlots in areas where there is an acute fuel wood shortage.[27]

A more recent Master Energy Plan 2034 was developed in 2018 with the aid of the International Renewable Energy Agency (IRENA).[28] The plan asserts that under a limited import scenario, 676 MW of domestic capacity must be secured if projected demand is to be met in 2034 while assuring adequate reserves. Under the policy's limited import 2 scenario, hydropower is to make up 120 MW of installed capacity by 2025.

There are no specific regulations pertaining to SHP in the country, nor is there available information on cost and specific financial mechanisms. Financial incentives for other off-grid renewable solutions are only available in the form of development finance, as demonstrated by projects funded from UNDP and the World Bank.[29]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The climate crisis is likely to affect the river flow rate in the country. This foreseen fluctuation will affect hydropower capacity factors and make predictions more difficult.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The hydropower resources of Eswatini have been well documented and with the 2007 electricity sector reforms a legal framework for the introduction of independent power producers has been created. However up until now multiple barriers have made the development of SHP in the country difficult. Some of the most noteworthy barriers include:

- Limited private sector investment;
- Reduced reliability of the national grid;
- Lack of a good overview of potential sites for refurbishment.

The enabling factors include:

- Renewed interest in hydropower as an energy source, as indicated through the recent studies on the Ngwempisi cascading project and the Lower Maguduza plant, suggesting that new developments may progress more positively in the future;
- Increasing electricity prices and the reduced reliability of the national grid have resulted in increased interest in rehabilitation of the old defunct hydropower plants; it can be expected that a number of sites will be economically feasible to rehabilitate.

Lesotho

Wim Jonker Klunne, Hydro4Africa

KEY FACTS

Population	2,125,268 (2019)[1]
Area	30,360 km^2 [2]
Topography	Lesotho is a small country surrounded by the Republic of South Africa. The lowest elevation in the country is at the junction of the Makhaleng and Orange (Senqu) Rivers (at the border with South Africa), which at 1,400 metres is the highest lowest point of any country in the world. Lesotho is the only country that lies entirely above 1,000 metres in elevation. The highest point is the peak of the Thabana Ntlenyana mountain, which reaches an elevation of 3,482 metres. Approximately one quarter of the land area is represented by lowlands located in the west and varying in height from 1,500 to 1,600 metres above sea level. The remaining three quarters are highlands running from north to south, while the central ranges, the Maluti, are spurs of the main Drakensberg, which they join in the north, forming a high plateau lying at 2,700–3,400 metres.[3,4]
Climate	The climate in the country is temperate with cool to cold winters and hot, wet summers. The maximum temperature can exceed 30 °C in the lowlands in January, whereas in the mountains the temperature can fall to -20 °C in the winter.[5]
Climate Change	Lesotho is expected to experience a change in temperature and precipitation patterns, towards drier and hotter conditions. In addition, the intensity and frequency of extreme events such as floods and droughts are expected to increase, especially in the western and northern lowlands. Water resources will be affected negatively by the reduction of precipitation and increase in temperature. This will result in an increase in evaporation losses and a decrease in runoff and groundwater recharge.[6]
Rain Pattern	Rainfall is seasonally distributed, with up to 85 per cent of the total received from October through April. Average annual precipitation is 788 mm, varying from 300 mm in the western lowlands to 1,600 mm in the north-eastern highlands.[5]
Hydrology	Two of the largest rivers in Southern Africa, the Orange (Senqu) River and the Tugela River, as well as tributaries of the Caledon River have their source in the northern region of Lesotho. The country is entirely located within the Orange River basin, with the Orange draining two thirds of the country and its tributaries the Makhaleng and the Caledon covering the rest. The Lesotho Highlands Water Project (LHWP) is an ongoing water supply project with a hydropower component, developed in partnership between the Governments of Lesotho and South Africa. It comprises a system of several large dams and tunnels throughout Lesotho and delivers water to the Vaal River System in South Africa. In Lesotho, it involves the Malibamatso, Matsoku, Senqunyane and Senqu Rivers.[4,5]

ELECTRICITY SECTOR OVERVIEW

Lesotho does not have any proven domestic reserves of oil, coal or natural gas and heavily depends on biomass fuels in the forms of wood, shrubs, animal dung and agricultural residues to meet the energy needs of the majority of the population. The other fuels consumed in significant quantities are mineral coal, liquefied petroleum gas (LPG) and paraffin.[7]

The electricity sector is relatively small with an installed capacity of 77 MW as of 2020 (Figure 1).[8,9] This mainly came from the 72 MW 'Muela hydropower plant linked to and managed by the Lesotho Highlands Water Development Authority (LHWDA) scheme to provide water to South Africa. Peak demand has been seen to reach 167 MW, forcing the Government to meet the deficit through imports from Mozambique and South Africa. In 2019/2020, the Lesotho Electricity Company (LEC) purchased 389.1 GWh from the 'Muela hydropower plant and imported 429.8 GWh from South Africa and 99.5 GWh from Mozambique.[10] When electricity demand is low, Lesotho exports excess electricity produced by 'Muela hydropower plant to ESKOM, due to the country's lack of electricity storage capacity.[7]

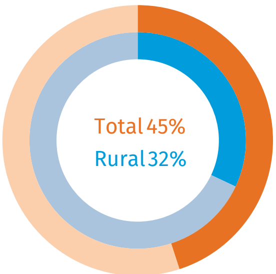
Figure 1. **Installed Electricity Capacity by Source in Lesotho in 2020 (MW)**

Source: Department of Energy,[9] Bureau of Statistics[10]

Hydropower generation in Lesotho has typically been a strong source of generation, but has experienced shortfalls in recent years. In 2018, generation from the 'Muela hydropower plant reached 515.8 GWh, but by 2019 this dropped to 391.7 GWh.[10] Small hydropower (SHP) plants, such as Semonkong, experience the highest generation in summer months. Most of the Semonkong generation in recent years has come from diesel generation, with only 0.06 GWh in 2018/2019 coming from hydropower, representing just 9 per cent of the plant's total electricity generation that year (0.7 GWh).[11] The Mantšonyane SHP plant generation in 2019/2020 was only recorded for January at 0.03 GWh.[10]

Nationwide, approximately 45 per cent of the population had access to electricity in 2019, a revision downwards of 5 per cent from 2018 estimates. Electricity access rates are 76 per cent for urban areas and 32 per cent for rural areas.[12]

Figure 2. **Electrification Rate in Lesotho in 2019 (%)**



Source: World Bank[12]

Besides hydropower, Lesotho possesses significant resources of other renewable energy sources. In preparation of the recent Scaling up Renewable Energy Programme (SREP) Investment Plan for Lesotho, the Government carried out a renewable energy resource assessment (Table 1).[9]

Table 1. **Technical Potential of Low Carbon Technologies in Lesotho under SREP**

Technology	Technical potential (MW)
Utility-scale wind power	2,077
Utility-scale solar PV	118
Micro-solar power technologies	38
Small-scale hydropower	36
Solar power micro-grids	31
Waste to energy	10
Solar power home systems	1
Floating micro-hydropower	0.5
Total	**2,311.7**

Source: Department of Energy[9]

The electricity supply industry in Lesotho is regulated by the Lesotho Electricity and Water Authority (LEWA). LEWA is an independent regulator responsible for issuing licences, approving electricity tariffs, setting and monitoring the quality of supply and service standards and resolving disputes between suppliers and customers. LEWA has the authority to regulate all aspects of the industry, including the generation, transmission, distribution, supply, import and export of electricity.[13]

Electricity is supplied by the Lesotho Electricity Company (LEC). LEC is a parastatal entity established under the Electricity Act 7 of 1969 and is empowered to distribute, transmit and supply electricity. In 2000, the Lesotho Utilities Sector Reform (LURP) unsuccessfully attempted to privatize LEC and to date the utility remains state-owned. The Lesotho Highlands Water Development Authority (LHWDA) is the agency responsible for the electricity generation from the 'Muela hydropower plant. The roles and responsibilities of these two bodies are set out in the 1993 Policy on the LHWDA/LEC interface.[9]

Electricity tariffs in Lesotho vary by consumption category and in 2020/2021 were as shown in Table 2.

Table 2. **Electricity Tariffs in Lesotho in 2022/2021**

Customer category	*Final electricity price (LSL (USD) per kWh)*	*Increase vs. 2017/2018 rates (%)*
Industrial high-voltage	0.2559 (0.017)	3.0
Industrial low-voltage	0.2767 (0.018)	3.1
Commercial high-voltage	0.2559 (0.017)	3.0
Commercial low-voltage	0.2767 (0.018)	3.1
General purpose	1.6608 (0.110)	3.8
Domestic	1.4782 (0.097)	3.8
Lifeline domestic	0.7273 (0.048)	–
Street lighting	0.8725 (0.057)	3.7

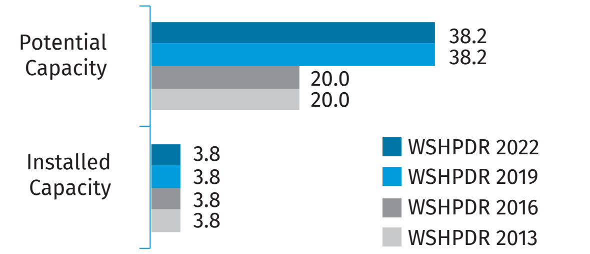
SMALL HYDROPOWER SECTOR OVERVIEW

SHP is defined in Lesotho as hydropower plants with capacity of up to 10 MW.[9] As of 2021, the installed capacity of SHP plants was 3.82 MW, of which 2.2 MW was operational, while the potential was estimated at approximately 38.2 MW.[15] Neither installed nor potential capacity estimates have changed since the publication of the *World Small Hydropower Development Report (WSHPDR) 2019* (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Lesotho (MW)**



Source: Jonker Klunne,[15] *WSHPDR 2013*,[16] *WSHPDR 2016*,[17] *WSHPDR 2019*[18]

There are five SHP plants in Lesotho: Mantsonyane (2 MW), Tlokoeng (670 kW), Katse (540 kW), Tsoelike (400 kW) and Semonkong (180 kW) (Table 1). However, out of these five, only the Mantsonyane and Semonkong plants are currently operational.[15] As of 2021, the Katse plant (on the Katse dam) is decommissioned due to earlier flooding. The Government of Lesotho engaged with the Japan International Cooperation Agency (JICA) to have it rehabilitated and connected to the national grid. The commencement of the work is expected sometime in 2022.[19]

Table 3. **List of Installed Small Hydropower Plants in Lesotho**

Name	*Location*	*Capacity (MW)*	*Head (m)*	*Plant type*	*Operator*	*Launch year*
Katse (non-operational)	Katse Dam	0.54	–	Reservoir	LHDA	2000
Tsoelike (non-operational)	Qacha's Nek	0.40	–	Run-of-river	LEC	1990
Tlokoeng (non-operational)	Mokhotlong	0.67	–	Reservoir	LEC	1990
Semonkong	Semonkong	0.19	18.0	Run-of-river	LEC	1989
Mantsonyane	Mantsonyane	2.00	35.5	Reservoir	LEC	1989

Source: Jonker Klunne[15]

The Tsoelike hydropower plant is a 400 kW run-of-river installation that was constructed to serve the town of Qacha's Nek in the south of Lesotho, close to the border with South Africa. It was commissioned on 5 February 1990 as part of French development assistance to Lesotho. The plant consists of two Francis hydropower turbine generation units, supplemented by a 200 kVA diesel generator set located on a ledge next to the power plant and a 320 kVA set at the town of Qacha's Nek. Qacha's Nek previously had an isolated electricity system, but has been connected to the South African ESKOM grid since 1997. This cross-border connection has enabled LEC to decommission the plant in 2000 as it was developing serious technical and siltation problems due to the design of the plant allowing silt to enter the system.

Tlokoeng is a 670 kW plant in the eastern part of the country, built with French development aid to serve the town of Mokhotlong. The plant has two Francis turbines of 460 kW and 210 kW capacity, augmented by two diesel generator sets as backup — one diesel set at the plant itself (200 kVA) and another of 500 kVA at Mokhotlong town. The plant was commissioned in February 1990 and over its operational life provided on average 27 per cent of the electricity demand of Mokhotlong, ranging from a low of 2 per cent in 1999 to a maximum of 47 per cent in 2000.[20] Originally designed for cyclic storage, equivalent for 27 hours output at full load, due to the siltation of the storage reservoir it effectively turned into a run-of-river plant. The plant is located on the Khubelu River and has seen a history of technical problems related to the bearing failures and exciter problems as well as flooding in 1996. It was decommissioned in November 2002 when the 33 kV transmission line from the Letseng diamond mine reached the town of Mokhotlong. Since then, plans have been tabled to use the plant for peak lopping and/or operation as an independent power producer (IPP), but no concrete steps have been taken to this effect. The difficult access situation and limited availability of spare parts for the original French equipment have inhibited the development of the site.

The Mantsony'ane hydropower plant was financed by a grant from Norway and handed over to LEC on 6 February 1989. It is located on the Mantsony'ane River in central Lesotho and is feeding the LEC grid through the Mantsony'ane substation on the 33 kV line Mazenod–Taba Tseka. The plant can operate on an isolated network if required, but the main operational strategy has been daily peak lopping. The plant is equipped with two Francis turbines of 1,500 kW and 500 kW, coupled with a 1,900 kVA and a 650 kVA generator, respectively. It features a storage reservoir on the river and an unlined 655-metre-long tunnel from the intake to the rock cavern power house. The design head is 35.5 metres. The power plant was flooded with water in November 2006 and was out of operation for a couple of years. It was later rehabilitated as part of the African Development Bank's Lesotho Electricity Supply Project.[21,22]

The Katse Dam, a concrete arch dam on the Malibamat'so River, is the second largest dam in Africa and is part of the Lesotho Highlands Water Project, which is planned to include five large dams in remote rural areas. Although the main purpose of the Katse Dam is water storage and diversion, a mini-hydropower plant is included. The plant is located 123 metres below the spillway level of the Katse Dam and consists of a horizontal Francis turbine and an 800 kVA synchronous generator. Since its commissioning in August 2000, the plant has been run in isolation from the LEC grid as the main power source for the Katse Dam electricity requirements. At the moment, the plant is not in use due to flooding damage and awaiting rehabilitation, which is expected to start in 2022.

The Semonkong hydropower project was designed for 180 kW of hydropower capacity supplemented by a 120 kW diesel generator. Currently, due to wear and tear on the Sorumsand Verksted turbine, the hydropower equipment is able to produce 125 kW only. The diesel generator has been upgraded twice since its installation and is currently a 180 kW Cummins unit. The Semonkong hydropower project, developed as part of a Norwegian development aid project, was commissioned in 1988 and officially opened in 1990. The plant powers an isolated mini-grid that serves the town of Semonkong and has 161 customers, consisting of 113 households and 48 commercial connections, all on prepaid meters. The Semonkong powerhouse was designed with provision for a second hydropower turbine. However, it will only be feasible to install this second turbine if a larger reservoir is constructed for increased water supply. The hydropower project comprises an intake structure, a headrace and penstock piping, a powerhouse and power generating equipment. The intake structure consists of a 100-metre-long concrete weir, a headrace inlet with a trash rack and a simple pipe with a light steel gate for the flushing of sediment in front of the intake. The low-pressure headrace is a 290-metre-long concrete pipe and the penstock is a 150-metre-long glass fibre-polyester pipe. A standard design, cast-in-place concrete surge chamber is located at the upstream end of the penstock.[23] Under the recently approved World Bank Lesotho Renewable Energy and Energy Access project, the Semonkong plant will be rehabilitated and hybridized with a 1.5 MW solar photovoltaic (PV) plant and storage of 500 kWh. This will allow the customer base to be expanded with an additional 100 customers.[24]

There is a substantial potential for further SHP development in Lesotho. Technical assessments for SHP potential were conducted as part of the Power Generation Master Plan in 2009, which proposed hydropower sites with a combined capacity of nearly 88 MW. These include eight SHP sites with a combined capacity of 36.33 MW. The technical potential of each proposed site was re-evaluated as part of the SREP Investment Plan for Lesotho. The analysis also covered the existing non-operational plants. The exclusion criteria for the technical analysis included urban areas, proximity to wetlands, protected areas, freshwater ecological protected areas and areas within 20 kilometres of the nearest transmission line. Four of the original 11 sites proposed in the Master Plan and the existing but non-operational SHP plant Tsoelike met the eligibility criteria. In addition, the analysis revealed one previously unidentified site (Table 4).[9]

As part of the preparatory work for phase 2 of the Lesotho Highlands Water Project (LHWP), feasibility studies were carried out on the inclusion of pumped storage, such as the Kobong plant. However, the decision was made to defer the pump storage option (due to prevailing economic conditions) and advance the conventional options. This entails one site at Oxbow on the Malibamatšo River and two sites on the Senqu River, all three in the large hydropower category.[25]

Table 4. **List of Small Hydropower Projects Available for Investment**

Name	Location	Potential capacity (MW)	Type of site (new/refurbishment)	Type of plant
Makhaleng 4	Makhaleng	9.1	New	Reservoir
Makhaleng 3	Makhaleng	8.9	New	Run-of-river
Hlotse	Hlotse	6.5	New	Reservoir
Phuthiatsana	Phuthiatsana	5.4	New	Reservoir
Thaba-Tseka	Mali-bamat'so	4.5	New	Reservoir

RENEWABLE ENERGY POLICY

The Lesotho Energy Policy 2015–2025 noted that renewable energy sources and energy efficiency are expected to play a significant role in the country's future energy plans and explicitly stated the Government's aim of improving access to renewable energy services and technologies. Strategies and programmes include facilitating the establishment of rural energy service companies (RESCOs) and developing a renewable energy programme to support fossil fuel substitution.[9]

In 2015, LEWA, with the support of the African Development Bank, prepared a draft Regulatory Framework for the Development of Renewable Energy Resources, which in particular covers feed-in tariffs, procurement guidelines and templates for various licences, tenders and power purchase agreements (PPAs). Many components of this framework have been incorporated in the Energy Act. Moreover, it is expected that the project of the United Nations Development Programme (UNDP) and the Global Environment Facility (GEF) Development of Cornerstone Public Policies and Institutional Capacities to accelerate Sustainable Energy for All (SE4All) Progress, which is currently ongoing, will assist in creating a more conducive environment for renewable energy.[26,27]

COST OF SMALL HYDROPOWER DEVELOPMENT

Costs of SHP remain high in the country, as elsewhere, since costs of SHP are higher per MW of installed capacity than larger hydropower plants.

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

Much of the financing for projects in the country are reliant on international development aid or project financing.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Poor rainfall in recent years has significantly impacted the hydropower sector, leading the few remaining operational SHP plants such as the Semonkong and the Mantšonyane to significantly decrease generation output. This makes for a poor SHP business case, and puts the future of the sector in jeopardy.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

In general, the conditions in Lesotho can be described as conducive in terms of the legislation framework allowing the operation of independent power producers and distributors.[28] However, it has proven to be difficult for international partners to find viable business models for the development of SHP in Lesotho. For example, Tarini Hydro Power Lesotho Ltd., a subsidiary of Tarini in India, has been trying for a couple of years now to start two hydropower projects (the 80 MW Oxbow and 15 MW Quithing projects) but still has not been able to commence construction works.[29]

However, with the renewed interest in renewable energy, and in particular mini-grids, promising signs are emerging. One of the solar mini-grid developers in the country is about to launch a GIS-based exercise to determine whether some of its solar mini-grids can be hybridized with SHP.

The key barriers to the development of SHP in Lesotho include:

- Poor water resources, leading to poor capacity factors for existing plants;
- Lack of effective infrastructure;
- Fragmented institutional responsibilities;
- Lack of integrated planning;
- A rather small size of the potential market and the limited ability to pay on the part of the rural population;
- Limited skills required for SHP construction, operation and maintenance;
- Low general awareness of SHP as well as of other renewable energy technologies;
- Difficulties in accessing some sites;
- Limited availability of spare parts in the local market;
- Low water levels mean that SHP is no longer viable and existing plants might not generate due electricity.

No clear enabling factors have been identified for the development of SHP in the country.

Namibia

Davy Rutajoga, International Center on Small Hydro Power (ICSHP)

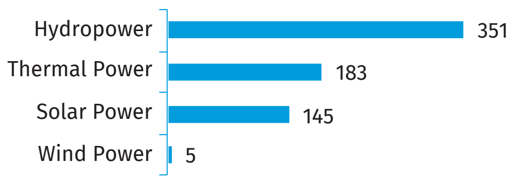
KEY FACTS

Population	2,540,916 (2020)[1]
Area	824,290 km^2 [2]
Topography	Namibia is characterized by four topographical regions: the Namib desert, the Central Plateau running from north to south with an altitude reaching up to 2,000 metres above sea level, the eastern lowlands that include the Kalahari Desert and, to the north-east, the high rainfall areas of Caprivi and Okavango. The highest mountain in the country is the Brandberg peaking at approximately 2,579 metres above sea level, followed by the Moltkeblick with a height of 2,480 metres.[3]
Climate	Namibia is one of the driest and most arid countries in Sub-Saharan Africa. Characterized by high climatic variabilities with constant droughts, variable temperatures, water scarcity and unpredictable rainfall patterns. With 92 per cent of the land area considered very arid, arid or semi-arid, Namibia is second only to the Sahara Desert in aridity on the continent. The annual temperatures in the country average between 14 °C and 24 °C, with the north averaging 22 °C and the southern coast below 16 °C. Apart from the coastal area, the highest temperatures occur in the wet season in drier areas and right before the wet season in wetter areas. The dry season, when the lowest temperatures occur, lasts from June to August.[4]
Climate Change	Namibia has been experiencing the effects of climate change through increased unpredictability and variability in rainfall patterns, frequent droughts and increased annual temperatures. This has been affecting agriculture, with droughts reducing agricultural productivity and thus leading to reduced income for farmers and death of livestock. The annual mean temperatures have been observed to be increasing since the 1960s, particularly at night-time. The frequency of days with maximum temperatures exceeding 25 °C and 35 °C has been increasing and the frequency of days with temperatures below 5 °C has been decreasing. An increase in overall rainfall scarcity as well as an increase in heavy rainfall events have been observed, with noted changes in onset, duration and intensity of rainfall.[4,5]
Rain Pattern	Due to the arid nature that characterizes Namibia, rainfall is scarce and highly variable and potential evaporation is approximately five times greater than average rainfall. The annual mean rainfall is 279 mm, varying from 650 mm in the north-east to less than 50 mm in the south-west. Rainfall in the Namib Desert area is extremely scarce. Mean monthly rainfall averages 62 mm, 66 mm and 55 mm in January, February and March, respectively. The rainy season in Namibia is from October to April, with minimal rainfall in May and September.[4]
Hydrology	Of the scarce rainfall received in Namibia, 83 per cent is evaporated, 14 per cent is lost through transpiration, 2 per cent is run off into rivers and 1 per cent seeps underground. Within one season, the country can lose 20–85 per cent of its water through evaporation. Namibia has five perennial rivers: the Orange, the Kunene, the Kavango, the Zambezi and the Kwando (also known as Linyanti and Chobe).[6]

ELECTRICITY SECTOR OVERVIEW

The main sources of electricity in Namibia are hydropower, solar power, thermal power and wind power. In 2019, these sources accounted for 71 per cent, 19 per cent, 9 per cent and 1 per cent, respectively, of total electricity production, which amounted to 1,818 GWh (Figure 1). As a country that relies heavily on imported electricity, Namibia imports over 60 per cent of the total electricity consumed from neighbouring countries through bilateral contracts with Eskom of South Africa, Zimbabwe and the Southern Africa Power Pool (SAPP).[7]

Figure 1. **Annual Electricity Generation by Source in Namibia in 2019 (GWh)**

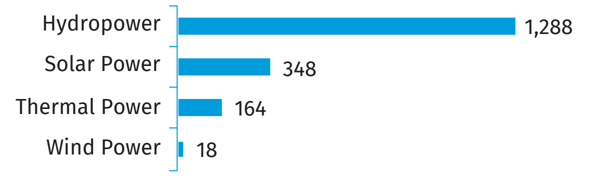


Source: IRENA[7]

In 2017, Namibia decided to update its Energy Policy of 1998 with a more future-oriented one — the National Energy Policy of 2017 (NEP). This new policy aims to usher in a more sustainability-focused approach to the energy sector, while acknowledging the country's reliance on neighbouring countries to meet most of its needs in electricity and the importance of developing and exploiting its own natural energy resources.[8] The NEP is aligned with the country's Vision 2030, an integrated long-term national development strategy that aims to improve the quality of life in Namibia to the level of developed countries by 2030.[10] In order to achieve this, the Government has been making efforts to attract foreign investment to develop the country's own hydrocarbon potential by establishing the country as an attractive destination for both international oil companies and local actors.

Much of the locally generated electricity in Namibia is produced by the Government-owned power utility NamPower, which operates the generation facilities: Ruacana hydropower plant, the Van Eck coal power plant, the Paratus diesel power plant and the Anixas diesel power plant.[9] As of 2020, Namibia had a total installed electricity capacity of approximately 684 MW, of which hydropower, thermal power, solar power and wind power represented 51 per cent, 27 per cent, 21 per cent and 1 per cent, respectively (Figure 2).[7]

Figure 2. **Installed Electricity Capacity by Source in Namibia in 2020 (MW)**



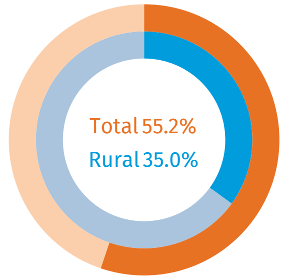
Source: IRENA[7]

NamPower, born out of the South West Africa Water and Electricity Corporation (SWAWEK) in 1996, controls the generation, transmission and supply of energy to the various Regional Electricity Distributors, mines and farms throughout the country. In an effort to be less reliant on imports from South Africa, NamPower has signed power purchase agreements with utilities in neighbouring Zambia, Botswana, Zimbabwe, Zambia, Mozambique and the Democratic Republic of the Congo (DRC). The company has also completed the TransCaprivi Interconnector which directly connects NamPower to the power grids of Zimbabwe and Zambia. NamPower is overseen by the Ministry of Mines and Energy (MME) and regulated by the Electricity Control Board.[11,12]

Since 2019, independent power producers (IPPs) can sell electricity to large power users both locally and internationally, across the national transmission grid. This marks a trend towards the decentralization of electricity production, transmission and supply in Namibia.[12]

The total electrification rate in Namibia was 55 per cent in 2019, with an urban access rate of 75 per cent and a rural access rate of 35 per cent (Figure 3).[13]

Figure 3. **The Electrification Rate in Namibia in 2019 (%)**



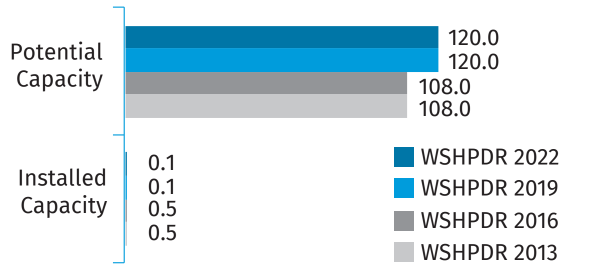
Source: AEP[13]

Electricity tariffs in Namibia are regulated by the Electricity Control Board (ECB), established by the Electricity Act 2 of 2000 and expanded by the Electricity Act 4 of 2007. The ECB's statutory functions are executed through the Technical Secretariat and include the reviewing, setting and approving of all tariffs in the country.[14] The cost of electricity for the end consumer depends on the location, electricity distribution company and specific tariff. In 2021–2022, NamPower distribution tariffs ranged between 1.29 NAD/kWh and 2.29 NAD/kWh (0.089–0.160 USD/kWh), with additional levies and charges applied.[15]

SMALL HYDROPOPOWER SECTOR OVERVIEW

There is no official definition of small hydropower (SHP) in Namibia, therefore, for the purposes of this chapter, a definition of up to 10 MW will be used. There is currently one operational SHP plant in Namibia, with a capacity of 50 kW. Plans have been devised to develop 13 more SHP plants in the country by exploiting the resources of the Orange River, which could have an estimated capacity of 120 MW and generate approximately 380 GWh/year. The installed and potential capacities have not deviated since the *World Small Hydropower Development Report (WSHPDR) 2019* (Figure 4).[16,17]

´Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Namibia (MW)**



Source: MME,[16] MEFT,[17] *WSHPDR 2013*,[18] *WSHPDR 2016*,[19] *WSHPDR 2019*[20]

The only operational SHP plant in Namibia is located between the village of Divundu and the Angola border, some 20 kilometres upstream the Popa Falls. There are a number of factors affecting the development of SHP including increasing drought periods, scarce rainfall and the location of potential sites at borders with neighbouring countries.[16]

RENEWABLE ENERGY POLICY

Namibia is one of the countries that experiences the highest solar irradiation regime, endowing it with tremendous potential for the development of solar power. The country also has considerable potential for the development of wind power due to strong winds in its coastal areas. There are also numerous hot springs in Namibia that could be harnessed for thermal power and rivers for hydropower development. In order to more efficiently exploit these natural resources for the development of the country, cohesive policies that would tie into the country's Vision 2030 were needed. The Government of Namibia formulated the Renewable Energy Policy (REP) of 2017 to boost the renewable energy sector and signal to local and potential international actors that the country is committed to invest in its natural resources.[21]

In order to implement the REP, further instruments such as the IPP framework and the Energy Efficiency Policy were introduced. The long-term National Integrated Resource Plan (NIRP), adopted in 2016, guides IPPs, power sector planners and electricity customers in Namibia. The REP also synthesizes elements of previously introduced policies such as the Fourth National Development Plan (NDP-4) 2012/2013–2016/17, the Off-Grid Energization Master Plan (OGEMP) of 2007, the National Policy on Climate Change of 2011 and the country's Intended Nationally Determined Contribution to the United Nations Framework Convention on Climate Change (UNFCCC).[21]

Namibia aims to achieve universal electricity access and a 70 per cent share of renewable energy in its generation mix by 2030, with all of it being locally produced. In order to stimulate and facilitate local and international investment in renewable energy in the country, the Government of Namibia introduced net-metering rules for installations that total up to 500 kW for all renewable energy technologies. Feed-in tariffs (FITs) on renewable energy were also introduced for projects that are between 500 kW and 5 MW in capacity, including solar power, biomass and wind.[21]

In addition to these policies, the Government of Namibia introduced the Solar Revolving Fund (SRF) in 1996 through the MME as part of the OGEMP. This fund offers subsidised loans to the citizens of Namibia at a fixed interest rate of 5 per cent per annum for five years. Through the SRF, photovoltaic pumps, solar home systems, solar water heaters and energy-efficient stoves are financed.[22]

Though there is no targeted support for hydropower, a number of funding opportunities by African institutions are being considered by the Government of Namibia to support renewable energy projects in general, including hydropower, such as the African Development Bank's Clean Energy Investment Framework for Africa, the Sustainable Energy Fund for Africa and the African Renewable Energy Fund.[21]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

In Namibia, SHP plants are regulated by the same legislation as larger hydropower projects. The main regulation and legislation documents regarding hydropower in Namibia are:

- The Electricity Act (2007);
- The Water Resources Management Act (2013);
- The S.W.A Water and Electricity Corporation Act (1980).

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

In Namibia, SHP development has been hindered by:

- High upfront capital costs exacerbated by high credit costs;
- Exchange rate fluctuations affect funding as the Namibian Dollar (NAD) is pegged by the South African Rand, which is subject to fluctuations affecting Namibia. As tariffs are set in NAD and foreign investment is in foreign currency, the devaluation of the NAD renders many projects costly;
- Insufficient government funding;
- Scarce inland water resources, as most of the important water resources are shared with neighbouring countries;
- Climate change is expected to exacerbate natural climate variability, creating more unpredictability of the hydrological regime;
- The legislation and policy in relation to SHP are unclear and need to be developed;
- Indigenous populations have concerns over displacement and other effects hydropower plant construction can have on their way of life.[5,21,23]

On the other hand, SHP development in Namibia is encouraged by:

- Government's interest in the exploitation of natural resources (solar, wind, thermal power) demonstrates an openness to maximizing the use of domestic resources, which could eventually include SHP;
- Government's interest in the development of renewable energy;
- National strategy aimed at making Namibia a hub for international investors in the energy sector;
- Trend towards the decentralization of the electricity sector that attracts local and international actors who can produce, transmit and supply electricity;
- Positive policy on renewable energy including renewable energy funds and FITs.

South Africa

Wim Jonker Klunne, Hydro4Africa; and Bohuslav Barta, Energy and Water Resources Engineering Consultant

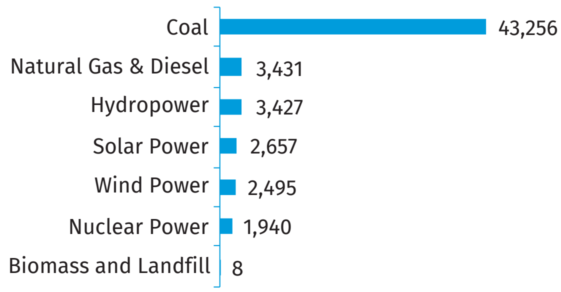
KEY FACTS

Population	59,620,000 (2020)[1]
Area	1,219,602 km^2 [2]
Topography	The territory of the country consists of a vast interior plateau rimmed by rugged hills and a narrow coastal plain. The elevation varies from approximately 1,500 metres above sea level in the dolerite-capped Roggeveld scarp in the south-west to 3,482 metres in the KwaZulu-Natal Drakensberg.[2]
Climate	South Africa is located in a subtropical region, though the Atlantic and Indian Oceans surrounding the country on three sides moderate its climate to warm temperate conditions. On the interior plateau, the high altitude (Johannesburg lies at 1,694 metres above sea level) keeps the average summer temperatures below 30 °C. In winter, night temperatures can drop to the freezing point.[2]
Climate Change	South Africa is already experiencing significant impacts of climate change, particularly as a result of increased temperatures and rainfall variability. Since 1990, the rate of increase of the national average temperature has been more than double that of global temperature increases in the same period. This increase is more pronounced for the western parts and the north-east of the country. There is evidence that extreme weather events in South Africa are increasing, with heat wave conditions found to be more frequent, dry spell durations lengthening slightly and rainfall intensity increasing.[3]
Rain Pattern	Average annual rainfall is 464 mm. Regional rainfall varies widely, from less than 50 mm in the Richtersveld (on the border with Namibia) to more than 3,000 mm in the mountains of the Western Cape. However, only 28 per cent of the country's territory receives more than 600 mm of rainfall. The Western Cape receives most of its rainfall in winter, while the rest of the country generally sees wetter summers.[2]
Hydrology	The country's largest river is the Orange River, which rises in the Drakensberg Mountains, traverses the Lesotho Highlands and joins the Caledon River between the Eastern Cape and the Free State. Other major rivers are the Vaal, Breede, Komati, Lepelle (previously Olifants), Tugela, Umzimvubu, Limpopo and Molopo.[2]

ELECTRICITY SECTOR OVERVIEW

Electricity production in South Africa is dominated by coal. During the 2020/2021 fiscal year, a total of 214,926 GWh of electricity was generated. Of this total, 13,526 GWh (6 per cent) was generated by independent power producers (IPPs) and the rest by plants operated by the public utility ESKOM, including coal-fired power plants producing 183,553 GWh (85 per cent), nuclear power producing 9,903 GWh (5 per cent), large hydropower producing 6,182 GWh (3 per cent), open-cycle gas turbines producing 1,457 GWh (1 per cent) and wind power producing 305 GWh (less than 1 per cent) (Figure 1). Electricity imports in 2020/2021 stood at 8,812 GWh.[4]

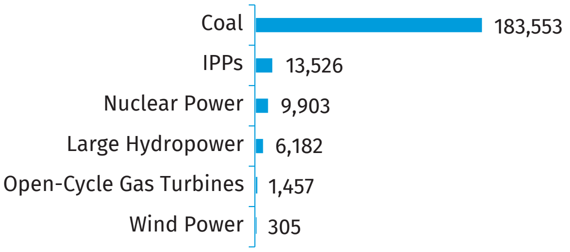
Figure 1. **Annual Electricity Generation by Source in South Africa in 2020/2021 (GWh)**



Source: ESKOM[4]

In 2021, the total installed capacity of South Africa was 57,214 MW, of which 43,256 MW (76 per cent) was represented by coal power plants, 3,431 MW (6 per cent) by natural gas and diesel power plants, 3,427 MW (6 per cent) by hydropower plants, 2,657 MW (5 per cent) by solar power plants, 2,495 MW (4 per cent) by wind power plants, 1,940 MW (3 per cent) by nuclear power plants and 8 MW (less than 0.1 per cent) by other sources including biomass and landfills (Figure 2). Approximately 89 per cent of total installed capacity was owned by ESKOM and the remaining 11 per cent was owned by Independent Power Producers (IPPs) and municipalities.[4]

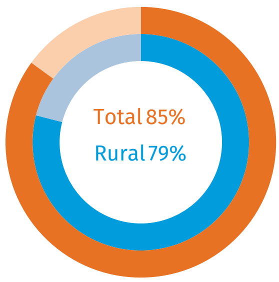
Figure 2. **Installed Electricity Capacity by Source in South Africa in 2021 (MW)**



Source: ESKOM[4]

Access to electricity across South Africa reached 85 per cent in 2019 (Figure 3). However, access to electricity in rural areas was only 79 per cent the same year and has been experiencing a decline since reaching nearly 84 per cent in 2014.[5]

Figure 3. **Electrification Rate in South Africa in 2019 (%)**



Source: World Bank[5]

The institutional framework of the electricity sector in South Africa includes the Department of Mineral Resources and Energy (DMRE) (previously Department of Energy) and the National Energy Regulator of South Africa (NERSA). The DMRE is responsible for establishing the policy, legal and regulatory framework for the energy sector. Its goal is to ensure the development, utilization and management of the energy resources in the country, aiming for the provision of secure, sustainable and affordable energy.[6] NERSA is mandated to regulate the electricity, piped gas and petroleum industries, it issues licences, sets and approves tariffs and charges, mediates disputes and ensures fair competition.[7] The South African National Energy Development Institute (SANEDI), carries out research and development activities to promote green energy technologies and energy efficiency.[8]

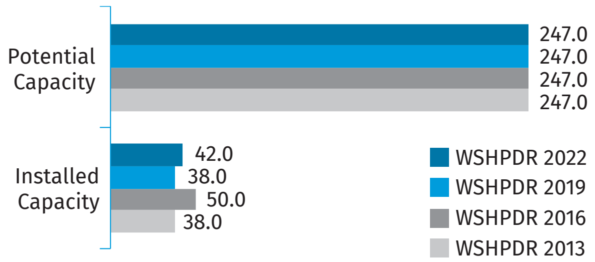
The electricity prices in South Africa depend on the supplier (ESKOM or municipality), the quantity of electricity used, the period (time or season) when the electricity is used, the volume of the supply, the geographic location of the customer, the voltage at which electricity is supplied and the cost of connecting to the supply. In 2021, average electricity prices rose to ZAR 1.349 ZAR/kWh (0.088 USD/kWh), an increase of nearly 16 per cent from 1.167 ZAR/kWh (0.076 USD/kWh) the previous year.[9,10]

SMALL HYDROPOWER SECTOR OVERVIEW

The Renewable Energy Independent Power Producers Procurement Programme (REIPPPP) is the main vehicle for the implementation of renewable energy technologies in South Africa, including small hydropower (SHP). During the first three bidding windows of the REIPPPP process, the maximum size of SHP plants was set at 10 MW. However, in the Request for Qualifications and Proposals for the third bidding window in June 2014, a new capacity limit of 40 MW was introduced for SHP.[11] A the same time, the draft Policy on Sustainable Hydropower Generation by the Department of Water and Sanitation (DWS) uses an upper limit of 10 MW.[12] As the DWS policy is not yet officially approved, the 40 MW as outlined in the REIPPPP process will be assumed as the current official definition of SHP in the country. However, for the purpose of comparison with the previous edition, this chapter will use data on hydropower up to 10 MW.

In 2021, the installed capacity of SHP up to 10 MW in South Africa stood at 42 MW, while potential was estimated at 247 MW.[13,14] Compared to the data cited in the *World Small Hydropower Development Report (WSHPDR) 2019*, potential capacity remained unchanged, while installed capacity increased by 1.8 per cent (Figure 4). The increase in installed capacity is due to one new SHP plant being commissioned in early 2021 on the As River.[13,15]

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in South Africa (MW)**



Sources: Jonker Klunne & Barta,[13] Barta,[14] *WSHPDR 2019*,[15] *WSHPDR 2013*,[16] *WSHPDR 2016*[17]

Note: Data are for SHP up to 10 MW.

Although not documented to a great detail, historically SHP used to play an important role in the provision of electricity to urban and rural areas of South Africa, particularly in the municipalities situated along the foothills of the Drakensberg mountain range. The first provision of electricity to the cities of Cape Town and Pretoria was based on SHP and also smaller towns started local distribution of electricity through isolated grids powered by SHP plants. However, with the expansion of the national electricity grid and the cheap, coal-generated power supplied through the grid, large numbers of SHP plants were decommissioned. A typical example is the Sabie Gorge hydropower plant with three

450 kW turbines, which was commissioned in 1928 to serve the town of Sabie in Mpumalanga and closed in 1964 after the area had been connected to the national ESKOM grid.[18] Between 1917 and the mid-1950s, some 150 pico- to mini-hydropower plants were installed in South Africa, with a few surviving plants currently being refurbished.

After approximately 30 years of neglecting the hydropower potential of the country, the first new SHP plant was commissioned in 2009 in the Sol Plaatje Municipality in the Free State province. Since then, 13 other hydropower plants have been developed in the country.[19,20] A list of currently operational SHP plants is displayed in Table 1.

The South African Renewable Energy Database, as developed by the Council for Scientific and Industrial Research (CSIR), ESKOM and the Department of Minerals and Energy, investigated the available renewable energy resources in the country, including the potential for hydropower.[21] As a follow-up, the resources available for the Eastern Cape region were detailed as part of a three-year investigative project entitled "Renewable energy sources for rural electrification in South Africa". The primary objective of the latter project was to identify the commercially viable opportunities for rural electrification in the Eastern Cape Province of South Africa using wind power, hydropower and biomass.[22]

The 2002 Baseline Study on Hydropower in South Africa, which was developed as part of the Danish support to the South African Department of Minerals and Energy, investigated the installed capacities of hydropower in South Africa and the potential for new developments. The study concluded that twice as much as the current installed hydropower capacity below 10 MW can be developed in the rural areas of the Eastern Cape, Free State, KwaZulu Natal and Mpumalanga.[23] A later 2011 publication gave new insights into the potential of SHP in South Africa by including the hydropower potential of water transfer systems and gravity-fed water system, mentioning a total potential of 247 MW, of which 15 per cent has been developed so far.[14]

SHP plants in South Africa can be divided into the following groups: 1) grid-connected plants commissioned prior to the REIPPPP process; 2) plants installed under the REIPPPP process; 3) grid-connected systems that fall outside the

REIPPPP process; and 4) stand-alone systems not feeding into the national grid.

The grid-connected SHP plants introduced prior to REIPPPP include the First and Second Falls, Ncora, Lydenburg, Friedenheim and Bethlehem hydropower plants. Financed by the former Transkei Government, four hydropower plants were built between 1980 and 1984 in the Eastern Cape on the Mbashe and the Tsomo Rivers and later handed over to ESKOM: Colley Wobbles, First Falls, Second Falls and Ncora. The First Falls plant has two 3 MW units with the provision for a future third machine and the Ncora plant has a single 1.6 MW unit.[24] The Lydenburg plant commissioned in 1982 has one Gilkes Pelton turbine of 2.6 MW. The system is operated by MBB of Nelspruit under a contract with the local municipality.[20] The Friedenheim plant consists of two Sulzer Francis turbines of 1 MW each. It is owned by the members of Friedenheim Irrigation Board and operated on their behalf by engineering firm MBB. It has been running since 1987 and sells the bulk of the generated electricity through a power purchase agreement (PPA) to the local Mbombela Municipality.[20] Bethlehem Hydro Pty Ltd owns two SHP plants that are normally referred to as "Bethlehem hydro": the 3 MW Sol Plaatje power plant near the town of Bethlehem, which was commissioned in November 2009; and the 4 MW Merino power plant close to the town of Clarens. These two plants were the first addition of hydropower generation capacity in the last three decades.[20] Both the Sol Plaatje and the Merino installations are dependent on the flow regime of the Lesotho Highlands Water Project (LHWP), the water transfer project supplementing the Vaal Dam storage in the Gauteng province with water from Lesotho. The Kruisvallei SHP plant (4.7 MW) is constructed on the same water source and saw the start of commercial operation in February 2021.

The Neusberg plant of Kakamas Hydro Electric Power is the first run-of-river SHP plant to be delivered under the REIPPPP programme and is located on the Orange River near Kakamas in the Northern Cape province. Although the plant has three 4.01 MW Kaplan turbines, it delivers 10 MW of baseload power to the national grid in order to qualify under the old requirements of the REIPPPP.[25,26] The construction of the plant began in June 2013 and its operation began in 2015.[27] The Stortemelk hydropower plant was developed as a greenfield project by REH Project Development (formerly NuPlanet Project Development). The plant, commissioned in 2016, has an installed capacity of 4.5 MW and has won several rewards, including for its architecture.[28]

The future of grid-connected systems is closely linked to the Government's policy on renewable energy development. The allocation in the IRP2010 and the REIPPPP of 195 MW (up from the original 75 MW) of SHP capacity is less than the estimated potential and might therefore limit SHP development. The future for SHP in South Africa will see two main parallel tracks: grid-connected projects that will feed into the national electricity system and small-scale systems for private use (not feeding into the grid, irrespective of whether a grid connection is available or not). These tracks can be supplemented by a third category of isolated systems for rural electrification purposes. Several project developers indicated an intention to submit hydropower projects for the fifth and sixth bidding windows. These included some larger plants along the Orange River and in the Eastern Cape Province. A number of grid-connected systems are in operation at the moment in South Africa that either deliver power to the national utility or use the national grid to wheel power to its customers, for example, the 44 kW Murludi SHP plant and the 2.3 MW L'Ormarins SHP plant.[20] Development of small-scale plants are expected to grow based on the foreseen raise in electricity prices and decreased reliability of the grid. The development of SHP potential can be realized if the Government fully recognizes and adheres to the public-private partnership (PPP) implementation process in developing the renewable energy resources.[12]

Recent years have seen efforts to utilize existing water infrastructure for SHP development. For example, the water utility Rand Water has some 15 MW of SHP investigated at its four pressure break stations. Buffalo City has a significant hydropower potential, as assessed in 2013, at its water supply and sanitation infrastructure.[29] However, none of the investigated sites have been developed so far. In 2015, a 15 kW pilot plant was installed at the Pierre van Ryneveld reservoir in Pretoria as part of a University of Pretoria research project, while Bloemwater, the water distribution company of the city of Bloemfontein, commissioned a 96 kW system at the inlet of a water reservoir that is now providing power to the company's headquarters.[30] Most recently, a 9 kW conduit "otter" hydropower plant has been installed by the City of Tshwane at the Doornkloof reservoir. Yet another recent project is the Kwa Madiba (50 kW) community plant on the Thina River in the Eastern Cape Province, developed as community-managed rural electrification project .[31,32]

The actual installed SHP capacity of South Africa is substantially larger than can be reliably assessed. The primary reason for this is the large number of privately-owned SHP plants operating on private property and disconnected from both the national and local grids. These plants are often associated with mines and their collective installed capacity is estimated at approximately 80 MW. In some cases, hydropower units are also used to provide mechanical power in support of mining operations, rather than electricity generation. In most cases, the technical specifications of these plants and their operational status cannot be confirmed and they are thus excluded from the SHP total.[13]

While many additional SHP projects have been considered, there are currently only two in advanced stages of planning, at Mpompomo Falls and Bivane. In both cases, an environmental impact assessment (EIA) has been carried out.[14] Additional details on the two projects are provided in Table 2.

Table 2. **List of Ongoing Small Hydropower Projects in South Africa**

Note: Data as of 2021.

Besides the operational plants, South Africa has a number of existing, inactive small-scale installations that could be refurbished, such as Belvedere (2.1 MW), Ceres (1 MW), Hartbeespoort (potential up to 8 MW), Teebus (up to 7 MW) and others.[14, 20] The Hydro4Africa database includes over 20 previously operational sites that have been abandoned or fallen into disrepair, in addition to 60 sites identified as suitable for potential development.[21] A short list of sites suitable for refurbishment is provided in Table 3.

Table 3. **List of Selected Potential Small Hydropower Sites in South Africa**

Name	*Location*	*Potential capacity (MW)*	*Head (m)*	*Type of site*

Bakenkop	Piet Retief	0.67	50	Refurbishment

Source: Barta,[14] Jonker Klunne[20]

Note: Data as of 2021.

The SHP sector in South Africa has recently received support from a number of initiatives. The Water Research Commission of South Africa has been supporting the University of Pretoria in implementing in-flow hydropower in water transfer and distribution systems.[33,34] Recent research conducted in the sphere of conduit hydropower technology application in South Africa investigated and proposed a generic method of evaluating hydropower potential in water supply infrastructure.[35] The potable water distribution system, where the mechanical energy of excess water pressure can be converted into electric energy, has been investigated in the City of Polokwane.[36] Under the SA-LED programme by the United States Agency for International Development (USAID), the !Kheis Local Municipality and the eThekwini Metropolitan Municipality have been supported in developing their hydropower resources.[37,38]

RENEWABLE ENERGY POLICY

South Africa has a full suite of policies in place regulating the energy sector: White Paper on the Energy Policy of the Republic of South Africa (December 1998), the National Energy Act (Act No. 34 of 2008), the Electricity Regulation Act (Act No. 4 of 2006), White Paper on Renewable Energy (2003) and Renewable Energy IPP Procurement Programme 2015.[8]

The commitment of South Africa towards emissions reduction, as indicated in the Intended Nationally Determined Contribution (INDC) to the United Nations Framework Convention on Climate Change (UNFCCC), has triggered the development of a Government-backed renewable energy procurement programme. In 2010, the Department of Energy presented the Integrated Resource Plan (IRP2010), outlining the electricity generation mix for the period up to 2030. The policy-adjusted development plan approved by the Cabinet set a target of 17.8 GW of total installed capacity for renewable energy by 2030. The main source of hydropower, as per the IRP2010, will come from imported electricity (approximately 2.6 GW by 2030), while local, small-scale hydropower and landfill gas-based electricity share an allocation of 125 MW.[39] In October 2019, an updated IRP was approved by the Cabinet. This IRP2019 sees an increased allocation of installed capacity for renewable energy, in particular wind and solar power, with a target of 8,288 MW of total installed capacity for wind power and 17,742 MW for solar power by 2030. However, the only hydropower allocation refers to imported electricity from the Inga3 hydropower plant in the Democratic Republic of the Congo.[40]

The energy mix scenario of the IRP is implemented through the REIPPPP, which was launched by the Department of Energy in 2011, switching from the feed-in tariff system that had been created in 2009. In the context of South Africa, renewable energy is very competitive and at the current stage does not require additional financial incentivization, with independent renewable energy operators being able to sell electricity to consumers at substantially lower prices than those of ESKOM.[13] The first three bidding windows of this programme were procured by 2015, after which the signing of the PPAs for the windows 3.5 and 4 was stalled until early 2018, causing a decrease in the interest in the renewable energy sector of the country, including from foreign investors. The signing of 26 outstanding PPAs in April 2018 brought new hope for renewable energy development in the country. In October 2021 the winning bids for bidding window 5 were announced, but did not include any hydropower projects.[41,42]

The REIPPPP process has initiated substantial activity in the hydropower sector. In total, over 19 MW of installed hydropower capacity has been procured from three hydropower plants (Table 4).[41]

Table 4. **Hydropower Capacity Procured under the REIPPPP**

Bidding window	*Hydropower plants*	*Capacity (MW)*
1	None	-

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The effects of climate change on water resources is expected to be highly variable, with changes to average annual runoff by 2050 predicted to range between -13 per cent and +48 per cent. While this suggests the median impact scenario will generate a moderate increase in runoff on the national scale, regions may be unevenly affected, with the Western Cape region expected to experience a decline in average annual runoff of 13 per cent by 2050, while areas with a projected increase in runoff, such as the east coast, are at risk of flooding. The well-developed national water distribution system is expected to play a major role in mitigating the regional shifts in water supply.[43] Regionally, increased unpredictability in runoff is expected to create disruptions to hydropower generation in neighbouring countries, on which South Africa partially depends for its own electricity needs.[44] Potentially, these factors could encourage further development in South Africa of SHP that is integrated into the national water distribution grid, as a means of both utilizing the domestic water transfers for generation and building additional resilience against expected disruptions to electricity imports.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The constraints hampering more extensive development of SHP in South Africa include:

- Lack of relevant legislation slowing hydropower development at non-powered dams;
- Lengthy and expensive process for a successful EIA;
- The Water Use Permit (as per National Water Act/No. 36 of 1998) is sometimes difficult to obtain;
- Difficulties obtaining an acceptable PPA;
- Difficulties obtaining permission for access to, or crossing of, private or state land;
- Prior possession of all other permits is a prerequisite for obtaining the National Energy Regulator licence;
- Local banks are not in favour of financing SHP projects.

Factors enabling SHP development in South Africa include:

- A well-established bidding vehicle for renewable energy projects (REIPPPP), in 2022 entering its sixth successive period of activity;
- Extensive research carried out in-country on implementing SHP solutions on existing infrastructure, including water distribution and transfer systems;
- A significant number of assessed potential sites for SHP projects, as well as previously decommissioned plants in need of refurbishment.

With regard to the above constraints, the developers interested in installing SHP plants tend to focus on the development of projects situated along the existing water distribution networks (mainly at the local Government level as the water use environmental permits are already in place) according to the PPP principles. All in all, it is expected that SHP can play a small but important role in the future energy mix of the country. The creation of a representative body (e.g., the country or regional SHP Association) would enable potential hydropower developers in the negotiation and technology implementation processes.

1.5. Western Africa

Countries: Benin, Burkina Faso, Cote d'Ivoire, Gambia, Ghana, Guinea, Liberia, Mali, Mauritania, Niger, Nigeria, Senegal, Sierra Leone, Togo

INTRODUCTION TO THE REGION

The Western Africa region straddles the Sahel zone and includes areas with arid and semi-arid climates, as well as areas abundantly supplied with water resources. Several countries in the region are major oil producers and thermal power is the leading source of electricity generation across most of Western Africa with the exception of Guinea and Liberia, where hydropower is the primary source of generation. In Burkina Faso, Côte d'Ivoire, Ghana, Mali, Nigeria, Sierra Leone and Togo, hydropower plays an important supplementary role, and some minor hydropower capacity exists in Benin. Gambia, Mauritania, Niger and Senegal lack hydropower of any kind.

The majority of countries in Western Africa have nationwide electricity access rates below 50 per cent, and a significant gap exists between the rates of electricity access in urban and rural areas. The development of renewable energy sources (RES) is increasingly prioritized by countries in the region, in part as a means of closing this gap. RES other than hydropower are represented in the region primarily by solar power and bioenergy, while Mauritania and Senegal have additionally invested in considerable wind power capacities. The Economic Community of West African States (ECOWAS) has been working to promote RES development in member states through the ECOWAS Centre for Renewable Energy and Energy Efficiency (ECREEE).

An overview of electricity sectors of the countries in the region is provided in Table 1.

Table 1. **Overview of Western Africa**

Country	*Total population (million people)*	*Electricity access, total (%)*	*Electricity access, rural (%)*	*Total installed capacity (MW)*	*Electricity generation (GWh/year)*	*Hydropower installed capacity (MW)*	*Hydropower generation (GWh/year)*
Benin	12	37	10	261	358	1	0
Burkina Faso	21	45	32	437	902	35	105
Côte d'Ivoire	26	49	N/A	2,229	10,613	879	3,481

Note: Data in the table are based on data contained in individual country chapters of the *WSHPDR 2022*; years may vary.

REGIONAL SMALL HYDROPOWER OVERVIEW

The most commonly used definition of small hydropower (SHP) in Western Africa is the definition established by the ECOWAS that includes plants with an installed capacity of up to 30 MW. This definition is adhered to in Benin, Gambia, Liberia, Mali, Nigeria and Sierra Leone. The up to 10 MW definition of SHP is used in Cote d'Ivoire and Senegal, while Guinea adheres to the up to 1.5 MW definition and Ghana to the up to 1 MW definition. No official definition of SHP exists in Burkina Faso, Mauritania, Niger and Togo.

A comparison of installed and potential SHP capacities in the region is provided in Table 2.

Table 2. **Small Hydropower Capacities by Country in Western Africa (MW)**

Country	*Local SHP definition*	*Installed capacity (local def.)*	*Potential capacity (local def.)*	*Installed capacity (≤10 MW)*	*Potential capacity (≤10 MW)*
Benin	Up to 30 MW	0.5	95.0	0.5	5.0*
Burkina Faso	N/A	N/A	N/A	4.6	246.0
Côte d'Ivoire	Up to 10 MW	5.0	45.7	5.0	45.7
Gambia	Up to 30 MW	0.0	N/A	0.0	19.5
Ghana	Up to 1 MW	0.1	9.9	0.05	17.4
Guinea	Up to 1.5 MW	N/A	N/A	11.2	751.8
Liberia	Up to 30 MW	4.9	592.0	4.9	4.9**
Mali	Up to 30 MW	5.7	154.7	5.7	5.7**
Mauritania	N/A	0.0	N/A	0.0	N/A
Niger	N/A	0.0	N/A	0.0	8.0
Nigeria	Up to 30 MW	57.2	734.3	N/A	N/A
Senegal	Up to 10 MW	0.0	0.0	0.0	0.0
Sierra Leone	Up to 30 MW	12.2	N/A	12.2	639.0
Togo	N/A	N/A	N/A	1.6	137.0
Total	**-**	**-**	**-**	**45.7**	**1,880.0**

Source: *WSHPDR 2022*[1]

Note: *For SHP up to 1 MW. **Based on installed capacity.

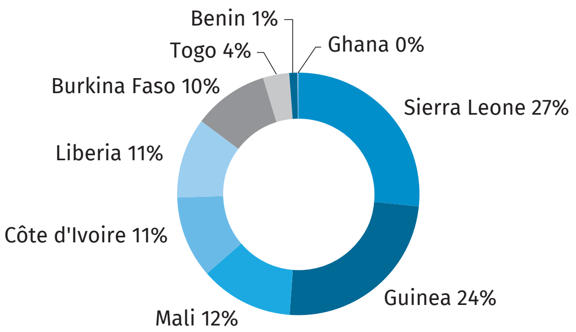
The total installed capacity of SHP up to 10 MW in Western Africa is 45.7 MW, while potential capacity is estimated at 1,880.0 MW. Relative to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed capacity has increased by approximately 4 per cent due to the commissioning of one new SHP plant in Burkina Faso. Meanwhile, the estimated potential capacity of SHP up to 10 MW has more than tripled, mainly as a consequence of new data on the SHP potential in Burkina Faso and Guinea as well as a reinterpretation of available data on the SHP potential in Sierra Leone.

Overall, SHP plays a relatively small role in the electricity generation of the countries in Western Africa. Across much of the region, existing hydropower capacities mostly comprise large hydropower plants, although in Sierra Leone SHP accounts for nearly 20 per cent of all hydropower capacity, and the hydropower capacity of Benin is fully comprised of SHP. Several countries in the region have no hydropower of any kind and little prospect for hydropower development due to climatic conditions. New SHP construction in Western Africa in recent years has been very limited, with development focusing on other RES. The impact of the COVID-19 pandemic has likely played a role in constraining the resources available for the expansion of SHP capacity in the region during 2020–2022. Consequently, recent activity in the SHP sector has mainly consisted of studies collecting data on SHP potential.

It must be also noted that reliable data on the SHP sector for countries in Western Africa are often very difficult to acquire, both in the case of the countries surveyed in the current report and in the case of those not covered in the report due to lack of data. Consequently, the review of recent activities related to SHP development in the region is likely not exhaustive.

The national share of regional installed SHP capacity by country is displayed in Figure 1, while the share of total national SHP potential utilized by countries in the region is displayed in Figure 2.

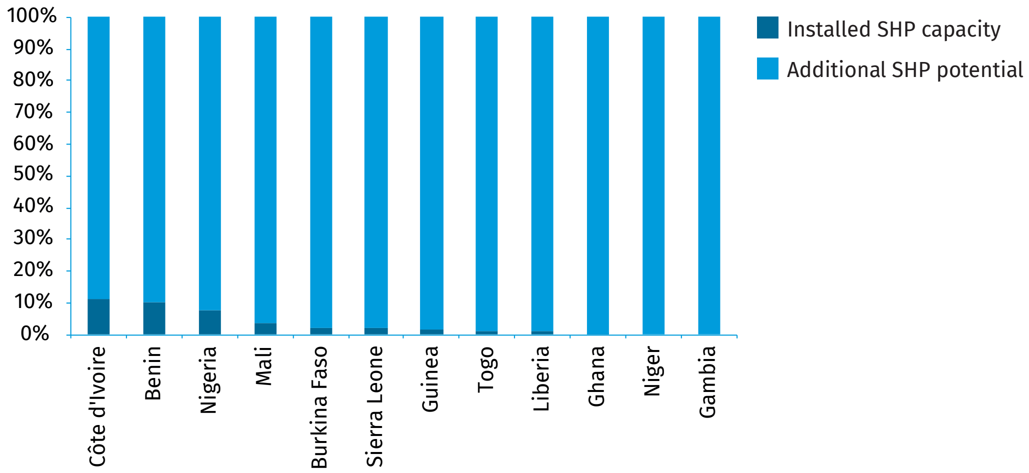
Figure 1. **Share of Regional Installed Capacity of Small Hydropower up to 10 MW by Country in Western Africa (%)**



Source: *WSHPDR 2022*[1]

Note: Gambia, Mauritania, Niger and Senegal not included due to a lack of SHP capacity; Nigeria not included due to a lack of data on existing capacities for SHP of up to 10 MW.

Figure 2. **Utilized Small Hydropower Potential by Country in Western Africa (%)**



Source: *WSHPDR 2022*[1]

Note: For SHP up to 10 MW, except in the case of Mali, Nigeria and Liberia, where the local definition is used due to lack of comprehensive data on the potential capacity of SHP up to 10 MW.

Benin has a single hydropower plant with an installed capacity of 0.5 MW. The potential capacity for SHP up to 30 MW is estimated at 95 MW, of which less than 1 per cent has been developed. Additionally, at least 5 MW of capacity for SHP up to 10 MW has been identified, of which 10 per cent has been developed. No recent activity in the country's SHP sector has taken place, although an upgrade to the existing SHP plant to raise its installed capacity to 1 MW has been considered.

The installed capacity of SHP up to 10 MW in **Burkina Faso** is 4.6 MW, provided by three SHP plants. The country's installed SHP capacity has recently doubled with the commissioning of a third plant in 2019. The potential capacity of SHP up to 10 MW is estimated at 246 MW on the basis of a recent study published in 2018, which identified a total of 80 potential SHP sites in the country. Specific plans exist outlining the construction of three additional SHP plants over the next several years.

The installed capacity of SHP up to 10 MW in **Côte d'Ivoire** is 5 MW, provided by a single SHP plant built in 1983, while the estimated potential SHP capacity is 45.7 MW, indicating that nearly 11 per cent has been developed. The country's installed SHP capacity has not changed in several decades. Additionally, the single existing SHP plant is non-operational and in need of refurbishment. No new projects in the SHP sector are under consideration, although some preliminary studies are planned.

There is no installed hydropower capacity in **Gambia** of any kind. The potential capacity for SHP up to 10 MW is estimated at 19.5 MW and remains entirely undeveloped. There are no SHP projects planned and recent activity in the SHP sector has been limited to updated studies of SHP potential, which have identified four potential SHP sites of up to 10 MW.

Ghana has a single SHP plant with an installed capacity of 0.045 MW. The potential capacity for SHP up to 10 MW is estimated at 17.42 MW, and at 9.9 MW for SHP up to 1 MW. Less than 1 per cent of SHP capacity under either definition has been developed. The sole operational SHP plant in the country was commissioned in 2020, and one earlier project has been on hold and requires extensive refurbishment. Sixty-nine potential sites up to 2 MW and another 12 sites up to 1 MW have been identified in the country, but there are no specific plans for new SHP construction.

The installed capacity of SHP up to 10 MW in **Guinea** is 11.2 MW, while the potential capacity has recently been estimated at 751.8 MW, indicating that approximately 1 per cent has been developed. There are five SHP plants in Guinea, with two undergoing renovation. As of 2021, feasibility studies were ongoing for the construction of four additional SHP plants with the support of the French Development Agency, and additional feasibility studies on several other potential sites are planned.

There are two operational SHP plants in **Liberia** with a total installed capacity of 4.86 MW. The potential capacity for SHP up to 30 MW in the country is estimated at 592 MW based on a study published in 2017, indicating that less than 1 per cent has been developed. No new construction in the SHP sector has taken place in recent years and there are currently no plans for additional SHP projects.

The installed capacity of SHP up to 30 MW in **Mali** is 5.7 MW, provided by a single plant. The potential capacity is estimated at 154.7 MW, indicating that nearly 4 per cent has been developed. Two new SHP plants are under development in the country through the Mini-Hydropower Plants and Related Distribution Networks Development Project, with environmental and social audits ongoing as of 2022. One additional SHP project has been initiated with the assistance of international development institutions.

There is no installed hydropower capacity of any kind in **Mauritania**, and no potential hydropower capacity has been documented. However, some limited SHP potential may exist in the southern part of the country.

There is likewise no installed hydropower capacity of any kind in **Niger**. A potential capacity of 8 MW for SHP of up to 10 MW has been identified but remains entirely undeveloped. There are no ongoing projects or plans for SHP development in Niger, although a large hydropower project of 130 MW is under construction.

The installed capacity of **Nigeria** for SHP up to 30 MW is estimated at 57.2 MW, with the decrease relative to the *WSHPDR 2019* reflecting more accurate data on existing SHP plants. There are 14 SHP plants operating in the country. The economically feasible potential capacity has been assessed at 734.3 MW from 278 potential sites, indicating that nearly 8 per cent has been developed, while the theoretical potential capacity is estimated at 3,500 MW. Several new SHP projects have been initiated in Nigeria over the last decade, but their status and stage of completion are unclear.

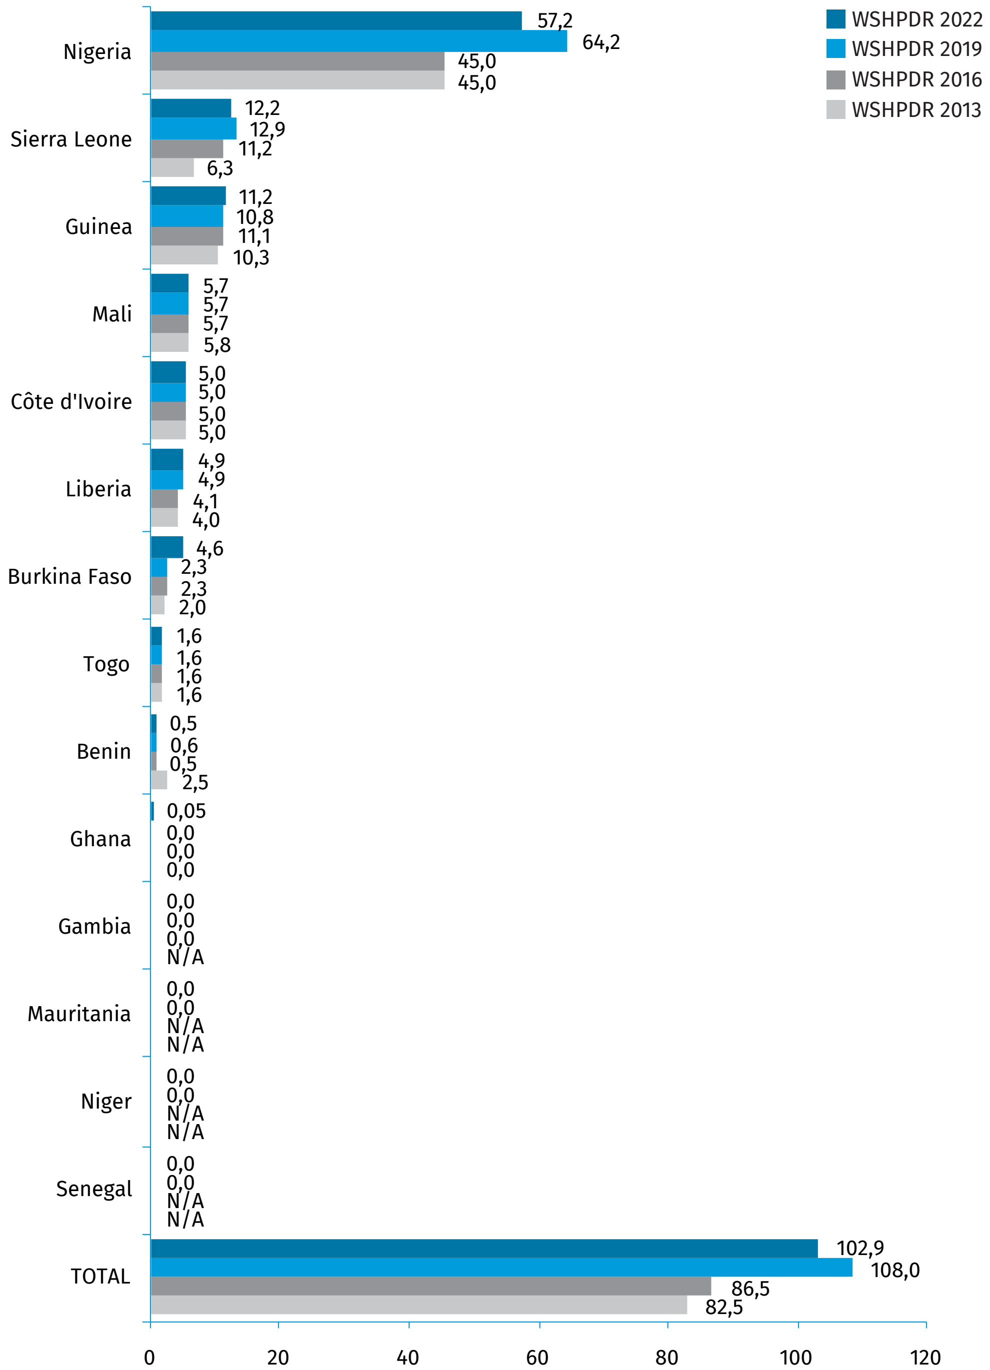
There is no installed hydropower capacity of any kind in **Senegal**, and no potential SHP capacity has been identified due to the flat topography of the country.

There are eight SHP plants of up to 30 MW in **Sierra Leone** with a total installed capacity of 12.15 MW. Potential capacity for SHP up to 30 MW is estimated at 639 MW, indicating that approximately 2 per cent has been developed. One new SHP plant with a capacity of 15.4 MW has been in development since 2016.

There is one SHP plant in **Togo** with an installed capacity of 1.6 MW. Potential capacity for SHP up to 10 MW is estimated at 137 MW, indicating that approximately 1 per cent has been developed, while potential for SHP up to 30 MW is estimated at 206 MW, of which less than 1 per cent has been developed. There are no ongoing SHP projects in the country, although the Government has identified seven potential sites for priority development.

Changes in the installed SHP capacities of the countries in the region compared to the previous editions of the *WSHPDR* are displayed in Figure 3.

Figure 3. **Change in Installed Capacity of Small Hydropower from *WSHPDR 2013* to *WSHPDR 2022* by Country in Western Africa (MW)**



Source: *WSHPDR 2022*,[1] *WSHPDR 2013*,[2] *WSHPDR 2016*,[3] *WSHPDR 2019*[4]

Note: For SHP up to 10 MW, except in the case of Nigeria, where the local definition is used due to lack of data on the installed capacity of SHP of up to 10 MW.

Climate Change and Small Hydropower

Precipitation and runoff in Western Africa have been highly variable over the last century. Projections of future runoff in the region are likewise uncertain. Runoff in certain countries, including Guinea, is projected to decrease, while in Gabon and Sierra Leone it is projected to increase. Development of additional hydropower capacity in the region is seen as essential to reaching a clean energy mix and universal electricity access, but increasing the share of hydropower without assessing the potential impacts of climate change may increase the exposure of countries in the region to climate hazards and put their energy security at risk. Nevertheless, studies in the Upper Niger and Bani River basins have highlighted potential solutions aimed at reducing high streamflow variability and loss of water resources. In particular, results suggest that operating hydropower facilities as run-of-river projects could reduce evaporation by 20 per cent.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The development of SHP in **Benin** is complicated by low and unstable streamflow in the country's rivers, as well as by a lack of institutional and regulatory frameworks, incentives for SHP development and local technical capacity. Additionally, the country has prioritized RES other than SHP in its renewable energy strategy. At the same time, the considerable untapped SHP potential, particularly for SHP up to 30 MW, may form the basis for feasible SHP projects in areas where electricity access is lacking.

The development of SHP in **Burkina Faso** is likewise hampered by unpredictable streamflow and droughts that are exacerbated by ongoing climate change. The country lacks incentives for SHP development, and lack of reliable information on SHP potential likewise discourages investments. Government support has instead focused on solar power, which is seen as a more sustainable and profitable option. Enablers for SHP development include the recently identified additional SHP potential as well as the country's experience with hydropower in general, including technical capacity in the design, manufacture and operation of hydropower plants.

The key barriers to SHP development in **Côte d'Ivoire** are the lack of comprehensive data on potential SHP sites and the country's heavy focus on the development of large hydropower. At the same time, the SHP potential in the country is considerable, and SHP could play an expanded role as the basis for micro-grids used to extend electricity access to remote areas.

Development of SHP in **Gambia** is hampered by the low heads found across the country's hydrology system, which complicates any hydropower development. Additional barriers include the institutional and operational weaknesses of the country's distribution and transmission system operator and high electricity tariffs, which make electricity unaffordable for large segments of the population and thus limit the economic feasibility of potential projects. Enablers include recent studies on SHP potential and the availability of incentives for SHP development in the form of feed-in tariffs (FITs).

Barriers to SHP development in **Ghana** include weak institutional and regulatory frameworks, limited local expertise and awareness of SHP, lack of funding opportunities and climate change impacts that interfere with hydropower generation. At the same time, a wide array of potential SHP sites has been identified in the country. The overall policy direction in Ghana is favourable towards SHP development and includes support in the form of FITs and other incentives.

Barriers to SHP development in **Guinea** include a lack of financial support and the low marketability of electricity from SHP due to the poverty of the rural population, as well as institutional shortcomings and lack of technical capacity in the sector. However, the undeveloped SHP potential in the country is considerable and well-documented. Some of this potential may be realized with the aid of international development agencies.

Development of SHP in **Liberia** is hampered by a lack of a comprehensive renewable energy policy or strategies for SHP development, deficient electricity grid, lack of local technical expertise and insufficiently detailed hydrological data. At the same time, there is considerable and well-documented untapped SHP potential in the country and recent government documents have made mention of plans to accelerate SHP development.

In **Mali**, SHP development is complicated by high investment costs, variability in river flow caused by climate change and concerns over environmental impacts, which have generated opposition from indigenous groups. Enablers for SHP development include the considerable untapped SHP potential and the availability of international financing, as well as interest on the part of the Government in promoting mini-grids and the job creation potential of SHP projects.

The lack of identified hydropower potential in **Mauritania** is a major impediment to SHP development in the country. The

Government has consequently focused on developing other RES such as solar power and wind power. However, if properly assessed, the suspected SHP potential in the southern part of the country may be used to provide power to isolated rural communities.

In **Niger**, the lack of experience with hydropower development and the country's irregular rainfall patterns, exacerbated by climate change, are the major obstacles to SHP development. Additional obstacles include a lack of a comprehensive renewable energy policy and dependence on fossil fuels for electricity generation. At the same time, the identified SHP potential could provide a means of improving electricity access, particularly if regional expertise in SHP could be attracted to develop this potential.

Barriers to SHP development in **Nigeria** include inadequate policy, institutional and regulatory frameworks, high investment costs and insufficient local technical capacity, lack of interest from the private sector in SHP development and limited access to available data on SHP potential. The main enablers are the very considerable and well-documented SHP potential and the urgent need to extend electricity access to remote parts of the country.

The main barrier to SHP development in **Senegal** is the country's flat topography and lack of any SHP potential. At the same time, if any SHP potential could be identified, it would benefit from a strong institutional framework and government support for RES development, which includes tax incentives and FITs.

Barriers to SHP development in **Sierra Leone** include a lack of funding and lack of local technical and manufacturing capacity, as well as high electricity tariffs that make electricity cost-prohibitive for many segments of the population. However, the country's considerable potential SHP capacity could be realized through international assistance and direct foreign investment, which have already made a positive impact in the solar power sector.

In **Togo**, obstacles to SHP development include barriers to the entry of private investors, institutional and regulatory weaknesses, relatively high up-front costs compared to diesel generators and lack of international funding opportunities. At the same time, the country has significant untapped SHP potential due to favourable hydrological conditions, and the Government has prioritized SHP development as part of rural electrification efforts, as well as attracting private investors to the SHP sector.

Benin

Salim Chitou, West-African Energy Information System

KEY FACTS

Population	12,114,193 (2020)[1]
Area	114,763 km^2[2]
Topography	The topography of Benin can be subdivided into five regions: the flat, low and sandy coastal region; the central hilly plain rising gradually to 200–400 metres from south to north; the Kandi Basin in the north-east, which is a plain drained by the Sota River and its tributaries; the Atakora Mountains lying in the north-west and peaking at Mount Sokbaro (658 metres); and the vast plains of Gourma in the extreme north-west.[2]
Climate	The climate of Benin is strongly influenced by the West African Monsoon. In the south, where the monsoon regime predominates (humid winds from the south-west), the climate is of the subequatorial type and is characterized by two rainy seasons and two dry seasons. In the north of the country, where the influence of the monsoon is more moderate, the climate is tropical continental, with one rainy season and one dry season. Air temperatures average 27.2 °C, with absolute maximums that can exceed 45 °C in the north.[3]
Climate Change	Benin is highly vulnerable to climate change. Since 1960, average temperature increased by 1.1 °C. The number of hot days per year increased by 39, whereas the frequency of cold days and nights decreased significantly. Annual precipitation decreased by 180 mm, resulting in more intense droughts. At the same time, rains intensified, leading to soil erosion and floods. The mean annual temperature is projected to increase by 1.0–3.0 °C by the 2060s and by 1.5–5.1 °C by the 2090s.[4]
Rain Pattern	Average annual precipitation ranges between 700 mm in the extreme north and 1,400 mm in the extreme south-east. There is also a transitional zone, where, depending on the year, the rainfall regime is bimodal as in the south of the country or mono-modal as in the north, with an average annual rainfall of 1,000–1,200 mm.[4]
Hydrology	Hydrologically, Benin can be divided into four major basins: the Niger Basin, the Ouémé-Yéwa Basin, the Volta Basin and the Mono-Couffo Basin. The Niger Basin comprises the Niger (120 kilometres), Mékrou (410 kilometres), Alibori (338 kilometres) and Sota (250 kilometres) Rivers. The Ouémé-Yéwa Basin includes the Ouémé River (510 kilometres) and its main tributaries the Okpara (200 kilometres) and Zou (150 kilometres), as well as Porto-Novo Lagoon (35 km^2) and Lake Nokoué (150 km^2). The Volta Basin includes the Volta (1,500 kilometres) and Pendjari (380 kilometres) Rivers. Finally, the Mono-Couffo Basin includes the Mono (100 kilometres) and Couffo (190 kilometres) Rivers, lakes Ahémé (78 km^2) and Toho (15 km^2) and Cotonou and Grand-Popo (15 km^2) Lagoons.[4]

ELECTRICITY SECTOR OVERVIEW

The total installed electricity capacity of Benin in 2019 was 261 MW, with over 98 per cent coming from thermal power. There is one hydropower plant installed on the territory of Benin, the 0.5 MW Yeripao plant, as well as 3.75 MW of capacity from micro-scale solar photovoltaics (PV) (Figure 1).[5] An additional 32.5 MW comes from the 65 MW Nangbeto hydropower plant installed on the Mono River in Togo, which is jointly owned by Benin and Togo under the bi-national Communauté Électrique du Benin (CEB).[5,6]

Total electricity generation in 2019 in Benin amounted to 357.5 GWh, coming predominantly from thermal power and to a lesser extent from solar power (Figure 2).[5] Conversely, the Yeripao hydropower plant did not contribute to the country's electricity supply as it remains offline.

Figure 1. **Installed Electricity Capacity by Source in Benin in 2019 (MW)**

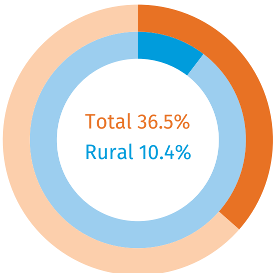
Source: SIE-Benin[5]

Figure 2. **Annual Electricity Generation by Source in Benin in 2019 (GWh)**

Source: SIE-Benin[5]

Total access electricity in the country in 2020 stood at approximately 37 per cent, including 65 per cent in urban areas and 10 per cent in rural areas (Figure 3).[7]

Figure 3. **Electrification Rate in Benin in 2020 (%)**



Source: DGRE[7]

The limited capacity of the country's energy sector to meet demand remains a major challenge for the public authorities. Until recently, the country's energy situation was characterized by a recurrent crisis marked by insufficient electricity supply, the relatively high cost of electricity, low energy efficiency, not to mention the weak development of alternative energy sources. These factors have made the sector particularly vulnerable and have negatively impacted the national economy. Hence, one of the key development objectives for Benin is to increase electricity production. The main recent development was the construction of the 127 MW Maria-Gléta thermal power plant, which was launched in 2019.[8] Benin and Togo jointly planned to develop the 147 MW Adjarala hydropower plant on the Mono River, however, the project stalled due to financing issues.[9] Currently, the Government plans to develop the 140 MW Glo-Djigbe thermal power plant, 100 MW of solar power capacity, the 128 MW Dogo hydropower plant and other projects.[10]

The main players of the electricity sector in Benin are the Ministry of Energy and the structures under its supervision, the Electricity Regulatory Authority (ARE), the Benin Agency for Rural Electrification and Energy Management (ABERME), the regional cooperation institutions, private structures responsible for the production, transmission, distribution and marketing of electrical energy and energy efficiency as well as consumer associations and professional organizations.

Electricity tariffs in Benin are uniform across the entire territory and remained unchanged between 2006 and 2019, but were adjusted for 2020 and 2021 (Table 1).

Table 1. **Low-Tension Electricity Tariffs in Benin in 2019–2021**

	2019 tariffs		*2020 tariffs*		*2021 tariffs*

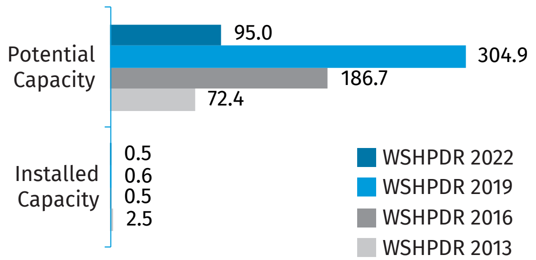
SMALL HYDROPOWER SECTOR OVERVIEW

The official definition of small hydropower (SHP) in Benin is up to 30 MW. There is one SHP plant in Benin, the 0.5 MW Yeripao plant (Table 2).[5] In 2016, the plant generated 5.3 MWh and in 2017, 1.2 MWh, with no generation since then. Renovations have been considered for the Yeripao plant to reach a capacity of 1 MW, however, the project was not realized. The SHP potential up to 30 MW is estimated at approximately 95 MW.[12] Compared to the *World Small Hydropower Development Report* (*WSHPDR*) *2019*, the installed capacity decreased based on more accurate data. The potential estimate also decreased based on a more recent assessment (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Benin (MW)**



Sources: SIE-Benin,[5] ECREEE,[12] *WSHPDR 2013*,[13] *WSHPDR 2016*,[14] *WSHPDR 2019*[15]

A number of studies of the hydropower potential in Benin have been carried out identifying a range of potential sites of various scale. In 2012, the ECOWAS Centre for Renewable Energy and Energy Efficiency (ECREEE) reported a total potential of 304.9 MW from 99 sites of up to 30 MW each, with the estimate being based on a number of earlier inventories.[16] Another assessment was carried out in 2015 under the ECOWAS Small-Scale Hydropower Programme using Geographic Information Systems (GIS) and identified 5 MW of potential for sites of up to 1 MW and 90 MW of potential for 1–30 MW sites.[12] The present chapter uses the more recent estimate of the potential.

RENEWABLE ENERGY POLICY

Benin is endowed with significant renewable energy resources, however, only a minor share of the existing potential is currently used. This issue is addressed in the National Policy for the Development of Renewable Energy (PONADER) 2020–2030, which was adopted by the Government on 14 October 2020. The ambition of the PONADER is in particular to improve knowledge of the renewable energy resources in the country, to promote technologies for the assessment of the existing potential, to reduce energy imports and to increase energy access in rural areas. The PONADER also set the target of reaching 20–30 per cent of electricity generation from renewable energy sources and 30–40 per cent of total installed capacity.[17] The Policy is aligned with the Government Action Programme (PAG), which among other objectives envisages improving the legislative and regulatory system in each sector in order to attract private investments.[10]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Several barriers to SHP development exist in Benin, including:

- Lack of local hydropower equipment, supply and local manufacturers;
- Lack of an institutional and regulatory framework facilitating licences, permits, authorizations and buy-back tariffs;
- Low-flow and drying rivers;
- Independent power producers have not yet explored the option of SHP;
- Lack of a feed-in tariff (FIT) for SHP;
- Policy focus on other renewable energy sources and large-scale hydropower.

At the same time, SHP development in the country could be possible given the following factors:

- Significant SHP potential remains untapped;
- Low electrification rates, particularly in rural areas.

Burkina Faso

International Center on Small Hydro Power (ICSHP)

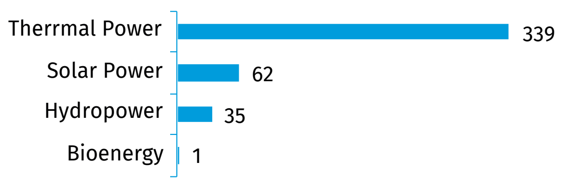
KEY FACTS

Population	20,903,278 (2020)[1]
Area	274,220 km^2 [2]
Topography	Burkina Faso is a landlocked country, bounded by Mali, Niger, Benin, Côte d'Ivoire, Ghana and Togo. It is situated on an extensive plateau, which is defined by a grassy savanna in the north that gradually becomes sparse forests in the south. A sandstone massif that covers most of the land is where the highest point of the country is, Mount Tena Kouron, at 747 metres. The lowest point of the country is the Black Volta River at 200 metres above sea level.[3]
Climate	Due to its location, Burkina Faso has a dry tropical climate. The climate alternates between a short rainy season and a long dry season. The country has three climatic zones: the Sahelian zone in the north, the North-Sudanian zone in the centre, and the South-Sudanian zone in the south.[4] April has the highest average temperature at 32 °C and the lowest average temperature is in January, at 25 °C.[5]
Climate Change	Burkina Faso is vulnerable to the impacts of climate change, particularly deforestation, desertification, low rainfall and extreme weather events. By 2050, a 1.4–1.6 °C rise in temperatures is expected in Burkina Faso.[6] By 2080–2099, temperature is projected to increase by 3–4 °C, which is substantially higher than the global.[5] Despite little projected change in annual precipitation sums, future dry and wet periods are likely to become more extreme.[6]
Rain Pattern	The Sahelian zone receives less than 600 mm of average annual rainfall. The North-Sudanian zone receives an average annual rainfall between 600 mm and 900 mm. The South-Sudanian zone receives an average annual rainfall above 900 mm.[3] Rainfall is heaviest in August, with an average of 231 mm, while the average annual precipitation is 816 mm.[5]
Hydrology	The three principal rivers are Black Volta (Mouhoun), the Red Volta (Nazinon) and the White Volta (Nakambé). These rivers all converge in Ghana to form the Volta River. The Oti, another tributary of the Volta, rises in south-eastern Burkina Faso.[6]

ELECTRICITY SECTOR OVERVIEW

In 2019, total electricity production in Burkina Faso reached 902 GWh, of which thermal power plants accounted for 82 per cent (Figure 1). The country is still highly dependent on electricity imports from Cote d'Ivoire, Ghana and Togo, having imported approximately 1,087 GWh in 2019.[7]

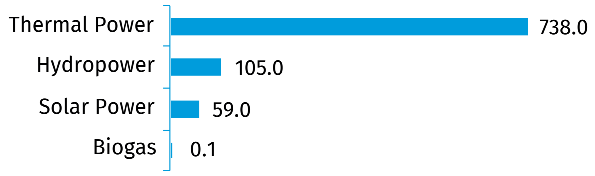
Figure 1. **Annual Electricity Generation by Source in Burkina Faso in 2019 (GWh)**



Source: ARSE[7]

In 2020, the total installed capacity in Burkina Faso was 437 MW, with thermal power (heavy fuel oil and distillate diesel oil) making up 78 per cent of the total and renewable energy sources accounting for the remaining 22 per cent (Figure 2).[8] Over the past years, the country has seen a significant increase in solar power capacity, with a number of new projects launched.[9]

Figure 2. **Installed Electricity Capacity by Source in Burkina Faso in 2020 (MW)**



Sources: IRENA[8]

The overall electricity losses in the country's electricity system amounted to 303 GWh in 2019, compared to 290 GWh in 2018, with most of the losses taking place in the distribution network. The overall efficiency of the electricity network improved from 84.4 per cent in 2018 to 84.8 per cent in 2019.[7]

The electricity demand of the country is constantly increasing and there are several projects under implementation aimed at improving the supply (Table 1). In 2019, agreements were signed with six independent power producers (IPPs) for the construction of solar power plants with a combined capacity of 140 MW.[7] The thermal power plant in Fada was also launched in 2020, contributing 7.75 MW to the country's installed capacity.[10] The country has also planned several other projects until 2030 as a commitment under its Nationally Determined Contribution.[11]

Table 1. **List of New Electricity Generation Projects under Implementation in Burkina Faso in 2021**

Project	*Planned capacity (MW)*	*Generation type*	*Connection*

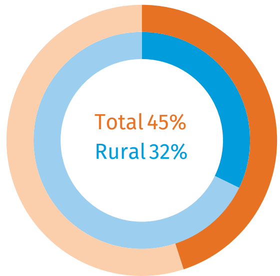
Source: ARSE,[7] MAN[12]

The energy sector in Burkina Faso is controlled by the Ministry of Energy, Mines and Quarries. The Regulatory Authority of Energy Sector (ASS) is responsible for regulation, control and monitoring of operators in the energy sector, while the Electricity Sector Regulatory Authority (ARSE) is the electricity sector regulator. The National Electricity Company of Burkina Faso (SONABEL) is the state-owned utility responsible for electricity generation, transport, distribution, import and export. As per the Electricity Law promulgated in 2017, SONABEL has lost monopoly in all subsectors except for electricity transport. The Rural Electrification Agency (ABER), created to replace the Rural Electrification Fund (FDE), aims to promote rural electrification in the country. The National Agency for Renewable Energy and Energy Efficiency (ANEREE) promotes and coordinates all operations aimed at promoting renewable energy and energy efficiency.[9]

Burkina Faso is one of the least electrified countries globally.[13] However, the electrification rate has been steadily increasing since 2010. In 2018, 45 per cent of the population had access to electricity (Figure 3). In urban centres, the electrification rate was 75 per cent, while in rural areas it was 32 per cent.[7] While more recent data on the country's electrification rate are not available, there has been a significant increase in rural electrification form 3 per cent in 2017 to 32 per cent in 2018.[7] By 2030, the Government aims to reach 95 per cent electricity access, including 50 per cent in rural areas, as well as 100 per cent and 65 per cent access to clean cooking solutions in urban and rural areas, respectively.[13]

Figure 3. **Electrification Rate in Burkina Faso in 2018 (%)**



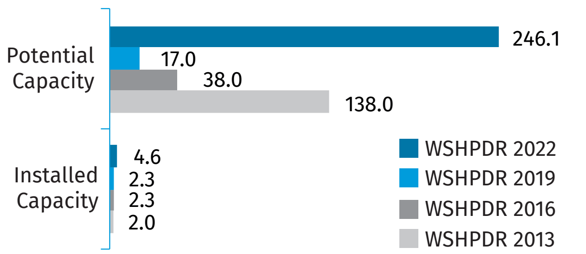
Source: ARSE[7]

The average electricity selling price in 2019 was 116.16 CFA/kWh (approximately 0.20 USD/kWh), 5 per cent less than in 2015. This was still below the cost of electricity generation of 139.11 CFA/kWh (0.24 USD/kWh), which results in a subsidy of CFA 22.96 (USD 0.04) per kWh consumed.[7]

SMALL HYDROPOWER SECTOR OVERVIEW

There is no official definition of small hydropower (SHP) in Burkina Faso. For the purposes of this chapter, SHP will be considered as plants up to 10 MW. As of 2021, there were three operational SHP plants with a combined capacity of 4.6 MW: Niofila (1.5 MW), Samandeni (2.6 MW) and Tourni (0.5 MW) (Table 2).[14,15,16] The change in installed capacity compared to the *World Small Hydropower Development Report (WSHPDR) 2019* is due to the launch of the Samendeni plant in 2019 (Figure 4). The estimate of the SHP potential has also increased based on a more recent study, which suggests a total potential of 246.1 MW. This includes 232.9 MW from 42 potential sites of 1.01–10 MW of capacity and 13.2 MW from 38 sites of 0.1–1 MW of capacity.[17]

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Burkina Faso (MW)**



Source: IRENA,[14] Africa Energy Portal,[15] Moner-Girona et al.,[16] Korkovelos et al.[17] *WSHPDR 2013*,[18] *WSHPDR 2016*,[19] *WSHPDR 2019*[20]

The Samendeni hydropower plant was launched in 2019 and is part of the Samendeni Valley Integrated Development Programme, an initiative by the Government of Burkina Faso.[15] The Government also expressed interest in conducting feasibility studies for the development of another three hydropower plants: the 5.0 MW Gongourou plant, 5.1 MW Bontioli plant and 7.8 MW Bon plant. The Ministry of Energy, Mines and Quarries declared the aforementioned projects as a priority for the sustainable development of the country. Commitments have also been made towards the construction of the Gongourou and Bontioli plants.[14]

Most of the hydropower projects planned or under construction are located on the Black Volta River.[21] Table 3 offers more information with regards to the Government's development initiatives in the hydropower sector.

RENEWABLE ENERGY POLICY

The National Policy for Sustainable Economic and Social Development outlined the strategy and actions of the Government of Burkina Faso for the period 2016–2020 to achieve its development objectives. The strategy mentions opting unequivocally for a transition towards green and renewable energy, in particular solar energy. In 2017, production and distribution of electricity in the country became open to private investors and SONABEL no longer has a monopoly over electricity production. Although power generation has been opened to the private sector, very few private investments have been made so far. As part of the Government's efforts to promote renewable energy and energy efficiency, ANEREE was established in 2016.[16]

Information in the field of renewable energy policy in Burkina Faso is enclosed in the Energy Sector Policy for the years from 2014 to 2025. The objectives the Government set in the Renewable Energy and Energy Efficiency Action Plans envisage Burkina Faso reaching 50 per cent renewable energy in the electricity mix by 2030, excluding biomass production.[13]

SHP projects are generally seen as more environmentally and socially acceptable in Burkina Faso and do not face negative social reaction as is often the case with large hydropower plants. The Government of Burkina Faso has been shown to be more invested in developing solar photovoltaic (PV) systems to increase electrification, particularly in rural areas, due to the country's climate which favours solar PV.

COST OF SMALL HYDROPOWER DEVELOPMENT

Based on the Bontioli, Gongourou and Samandéni projects, the investment costs for SHP projects in the country have been estimated at 11,006 USD/kW and the annual operation and maintenance cost at 330.2 USD/kW.[14]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

There are multiple barriers concerning SHP development in Burkina Faso. The most relevant ones include:

- Access to water as well as unpredictable climate conditions, with droughts affecting the regular flow of rivers and negatively influencing the profitability of potential SHP projects;
- The Government has mainly focused on solar power development in recent years, which is seen as a more sustainable and profitable solution, while SHP dissemination is not a priority;
- Lack of financial incentives such as feed-in tariffs and lack of sufficient information in the sector to attract potential private investors;
- Lack of reliable data from feasibility studies due to lack of funding and financial difficulties.[7,19]

Enablers for SHP development in Burkina Faso include:

- The hydropower sector development, including SHP projects, is actively encouraged by the Government, with a number of committed and planned SHP projects;
- Due to a number of existing hydropower plants in the country, there is experience in construction and operation of hydropower plants, as well as a qualified workforce for design, construction, operation and maintenance.

Côte d'Ivoire

N'guessan Pacôme N'Cho, Ministry of Petroleum, Energy and Renewable Energy

KEY FACTS

Population	25,716,544 (2019)[1]
Area	322,632 km^2[2]
Topography	Côte d'Ivoire is characterized by low terrain; the lands consist largely of plateaus and plains. The west highlands have few peaks beyond a thousand metres and the highest peak is Mount Nimba at 1,752 metres. In the remainder of the country, elevations generally vary between 100 and 500 metres, while most plateaus are approximately 200–350 metres.[3]
Climate	There are three main climatic regions: the equatorial coast in the south, the tropical forest in the middle and the semi-arid savannah in the north. Temperatures range from 10 °C to 40 °C, averaging 25-30 °C, but the country is generally subjected to large variations in temperature between the north and south and throughout the year. The south is generally warmer with high humidity between 80 and 90 per cent. The north is generally cooler with lower humidity between 40 and 50 per cent. Temperatures in the north change by up to 20 °C both daily and annually.[2]
Climate Change	Côte d'Ivoire is not yet seriously affected by climate change, but the balance could tip at any moment and harm the country's economy. Côte d'Ivoire could become one of the African continent's champions in adapting its economy to the phenomenon and mitigating its effects. Like the vast majority of countries on the African continent, the nation's contribution to the greenhouse effect is marginal. By 2050, it is projected that the country will be confronted with the combined effect of increase in temperatures (+2 °C), variation in rainfall (-9 per cent in May and +9 per cent in October), and rising sea levels (30 cm).[4]
Rain Pattern	The south has variable rainfalls between 2,100 mm and 2,500 mm. The middle central region has lower rainfalls of approximately 1,100 mm. The north is subject to a single rainy season lasting from April to October and peaking in August. The rainfall is higher in the north-west (approximately 1,600 mm) than in the north-east (approximately 100 mm). The western mountainous region is characterized by a nine-month rainy season (from February to October) with rainfall between 1,600 mm and 2,300 mm.[5]
Hydrology	The river system of Côte d'Ivoire has four main basins: the Cavally (700 km long with a drainage basin of 15,000 km^2); the Sassandra (650 km long with a drainage basin of 75,000 km^2); the Bandama (1,050 km long with a drainage basin of 97,000 km^2); and the Comoé, (1,160 km long with a drainage basin of 78,000 km^2). There are also several small coastal rivers: the Tabou, San-Pedro, Niouniourou, Boubo, Agnéby, Mé, Bia and Tanoé; and other smaller rivers such as the Gbanhala, Baoulé, Bagoué, Dégou, Kankélaba, Koulda, Gbanlou, Gougoulo and Kohodio.[6]

ELECTRICITY SECTOR OVERVIEW

Biomass dominates the energy sector of Côte d'Ivoire accounting for up to 70 per cent of overall energy needs.[7] Biomass fuels include: charcoal for households; firewood for households, small restaurants, bakeries and craft centres; agricultural and forest residues for the production of steam and/or electricity in some agro-industrial companies and sawmills.

Figure 1. **Annual Electricity Generation by Source in Côte d'Ivoire in 2019 (GWh)**

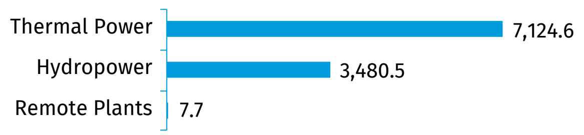
Source: CIE[8]

In 2019, the total electricity generated from all sources was 10,612.8 GWh. This comprised 7,124.6 GWh from thermal power plants, 3,480.5 GWh generated from hydropower and 7.7 GWh from remote plants (Figure 1). Electricity sales to countries in the region amounted to 1,179 GWh, while energy purchases were estimated at 17 GWh.[8]

Electricity generation in Côte d'Ivoire is from two main sources: hydropower contributing 879 MW of installed capacity (approximately 39.4 per cent) and thermal power plants contributing 1,350 MW (approximately 60.6 per cent) (Figure 2). The three following Independent Power Producers (IPPs) own 1,220 MW, or more than 92 per cent, of the total thermal power plant capacity: CIPREL (569 MW), Azito Energie (441 MW) and Aggreko (210 MW). There are also remote plants with generators running on diesel that supply some localities via mini-grids.[8] Their number decreased from 44 in 2018 to 40 in 2019 due to the connection of four localities to the interconnected grid. The installed capacity of these generators is 5,566 kVA or approximately 4.55 MW.

Since the end of 2017, the installed and available capacity supplying the interconnected electricity grid has been 2,229 MW. By March 2021, the installed capacity had not changed since the *World Small Hydropower Development Report (WSHPDR) 2019* in part due to projects being delayed due to COVID-19. The latest power plant in the country was commissioned on 2 November 2017. However, several electricity production units are scheduled for commissioning, including: the 37.5 MW solar photovoltaics (PV) project in Boundiali, which is scheduled to be commissioned in December 2021; the Azito thermal power plant (Phase 4) with combined cycle of 253 MW, the full commissioning of which is scheduled for April 2022; the GRIBOPOPOLI hydropower project of 112 MW, the commissioning of which is scheduled for the second quarter of 2023; and the SINGROBO-AHOUATY hydropower project of 44 MW and the associated energy evacuation network whose commissioning is scheduled for the first quarter of 2023.

Figure 2. **Installed Electricity Capacity by Source in Côte d'Ivoire in 2021 (MW)**



Source: CIE[8]

Out of a total of 8,518, the number of localities electrified in 2019 was 5,859 against 4,940 in 2018. This represented a coverage rate (ratio of the number of electrified localities to the total number of localities) of approximately 69 per cent in 2019 compared to 58 per cent in 2018. In terms of electricity access, the rate of the population living in an electrified area was approximately 94 per cent at the end of 2019 compared to 89.5 per cent in 2018.[9]

Regarding the distribution of electricity, there are two voltage levels for electricity subscribers: the low voltage is intended for households and the medium voltage is intended for companies or factories. The number of subscribers to the low-voltage electrical service increased by approximately 16 per cent between December 2018 and December 2019 from 2,191,290 to 2,532,418. Based on these data, it is estimated that the share of households with access to electricity was 49 per cent in 2019 compared to 44 per cent in 2018.[8] Information regarding rural electrification is not officially available due to the arbitrary nature of rural/urban distinctions in the country.

To accelerate the pace of improvement of the living conditions of the populations, the Government launched, following the instructions of His Excellency Mr. Alassane Ouattara, President of the Republic, the Government Social Programme (PSGouv) for the period 2019-2020. This programme was an intensifier of state social action and targeted all sectors.[10] Regarding access to electricity, the key outcomes of the programme were the reduction in the social tariff for the most disadvantaged households, improved rural electrification and connection/subscription at a lower cost. Thus, the main objectives of the PSGouv in terms of access to electricity were as follows: 1) the downward adjustment of 20 per cent of the nominal social tariff for the customers subscribing to the "social domestic" regime, in order to benefit from a reduction in the cost of electricity; 2) electrification of all of the 1,838 localities with more than 500 inhabitants by 2020 as part of the National Rural Electrification Programme (PRONER), with a target of 917 localities in 2019 and 921 in 2020; 3) facilitation of the connection/subscription to the national electricity grid of 400,000 households eligible for the Electricity For All Programme (PEPT) by the end of 2020, i.e. access to electricity for a population estimated at 2.4 million inhabitants.[9]

Under the technical supervision of the Ministry of Petroleum, Energy and Renewable Energy and the financial supervision of the Ministry for Economy and Finance, several public and private organizations are responsible for various activities in the electricity sector, including the General Directorate of Energy, which defines and implements the national energy policy. Two state companies are involved in the electricity sector: the Society of Energies of Côte d'Ivoire (CI-ENERGIES) and the National Electricity Sector Regulatory Authority (ANARE-CI). CI-ENERGIES is responsible for the planning and implementation of investment projects, while ANARE-CI plays the role of the electricity sector regulator. ANARE-CI was created by decree No. 2016-785 of 12 October 2016 and is vested with more extensive powers of decision, injunction, investigation and sanction to allow better regulation of the electricity sector.[11] As such, the missions assigned to it are in particular: to monitor compliance with laws and regulations as well as obligations resulting from authorizations or agreements in force in the electricity sector; to preserve the interests of users of the public electricity service and to protect their rights; to propose applicable tariffs to the Government in the electricity sector, including network access tariffs; to settle disputes in the electricity sector, in particular between operators and users; and to advise and assist the Government in the regulation of the electricity sector.

The Ivorian Electricity Company (CIE), established in 1990, is a private company responsible for the generation, transmission, distribution, export, import and management of electricity. It is linked to the state by a concession agreement for the public service of electricity for a period of 15 years, which was renewed in 2005 until 2020.[11] Three private operators (CIPREL, Azito Energie and Aggreko) are also involved in the sector as IPPs. They operate thermal power plants fuelled by natural gas supplied by PETROCI–C11, Foxtrot International and CNR International through contracts of sale and purchase signed with the Government.

The strengthening of electricity transmission and distribution infrastructure enabled the sector to have in 2019 an electrical grid with a total length of 54,017 km comprising: low-voltage lines measuring 22,523 km, medium-voltage (15 kV and 33 kV) lines measuring 25,432 km and high-voltage (90 kV and 225 kV) lines measuring 6,062 km.[8]

The Government has adopted a Strategic Development Plan 2011–2030, which covers the development of all sectors including the electricity sector. Within this framework, several projects have been planned concerning electricity generation, transmission and distribution infrastructure.

The electricity base tariffs are fixed by the Government upon the proposal of the regulator. Tariffs are the same for the entire country regardless of the region (Table 1).[12]

Table 1. **Electricity Tariffs under the Post-Payment Scheme in Côte d'Ivoire in 2019**

Tariff base	*Cost excluding 18 % VAT (CFA franc/kWh (USD/kWh)*
Social household low-voltage price (consumption ≤ 80 kWh in a two-month period)*	28.84 (0.057)
Social household low-voltage price (consumption > 80 kWh in a two-month period)	50.16 (0.100)
General household low-voltage price (consumption ≤ 180 kWh/kVA in a two-month period)	66.96 (0.133)
General household low-voltage price (consumption > 180 kWh/kVA by two-month period)	58.04 (0.116)
General professional low-voltage price (≤ 180 kWh/kVA)	86.31 (0.172)
General professional low-voltage price (> 180 kWh/kVA)	73.40 (0.148)

Source: ANARE-CI[11]

Note: *Exempt from VAT

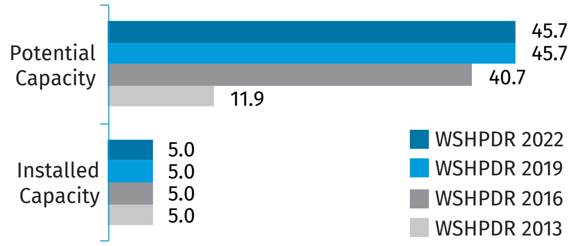
In addition to these base tariffs, there are additional taxes such as a fixed fee for a two-month period, a fee for rural electrification, the Ivorian Radio Television fee and local taxes that vary according to the electricity subscription and the region. Article 2 of Inter-ministerial Order No. 002 of 2 January 2019 stipulates that tariffs shall be revised upwards by 31 March of each year for application on July 1 of that year.[11]

SMALL HYDROPOWER SECTOR OVERVIEW

The official definition of small hydropower (SHP) is less than 10 MW as adopted by the General Directorate of Energy. The country's 5 MW of SHP installed capacity has remained unchanged since the *WSHPDR 2013*; however, estimated potential has increased by approximately 280 per cent, though remained unchanged since the *WSHPDR 2019* (Figure 3, Table 2).

There exists a single SHP plant Côte d'Ivoire, Grah/Faye, which was built in 1983.[13] Since 2018, the plant has been shut down and currently is in need of refurbishment. Thus, there was no available SHP capacity in the country as of Q1 2021.

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Côte d'Ivoire (MW)**



Source: SIEREM,[13] *WSHPDR 2013*,[14] *WSHPDR 2016*,[15] *WSHPDR 2019*,[16] CIE[17]

Table 2. **List of Operational Small Hydropower Plants in Côte d'Ivoire**

Name	*Location*	*Capacity (MW)*	*Head (m)*	*Plant type*	*Operator*	*Launch year*
Grah/Faye	35 km north of the town of San Pedro	5	10	Reservoir	CIE	1983

Source: SIEREM[13]

No SHP projects are currently underway. However, some preliminary studies are expected to be carried out, in particular those planned within the framework of the ENERGOS 2 project, which were delayed due to COVID-19.

Studies conducted in previous years have identified the most promising hydropower development projects. Table 3 consolidates data on sites with an estimated capacity less than 10 MW.[18,19] Based on these studies, dating back to 1979 (and to date the only studies), the total potential capacity for SHP is estimated at 45.7 MW suggesting that less than 11 per cent of the country's SHP potential has been developed. So far, these are the only studies conducted on SHP potential in the country.

Several large hydropower sites have been identified for a progressive development between 2017 and 2025: Soubré (275 MW), Singrobo (44 MW), Gribo-Popoli (112 MW), Boutoubré (156 MW), Louga (280 MW), Daboitié (91 MW), Tiboto (180 MW).[20] For hydropower of all sizes there is a total potential of 1.85 GW on the four major river basins, two times the current hydropower installed capacity.[11] The Soubré hydropower plant (275 MW) has been built and was officially put into service in November 2017. Regarding the Gribo-popoli (112 MW) and Singrobo (44 MW) hydropower plants, the Government has already signed concession agreements for their development.

Table 3. **Small Hydropower Sites Available for Renovation or Development in Côte d'Ivoire**

Name	*Location*	*Potential capacity (MW)*	*Head (m)*	*Type of site (new/ refurbishment)*
Grah/Faye	35 km north of the town of San Pedro	5.00	10.0	Refurbishment
Bandama	Haut Bandama	7.44	20.0	New
Lokpoho	Ferkessedou-gou	7.32	11.0	New

RENEWABLE ENERGY POLICY

During the period 2013–2030, as part of the Strategic Development Plan 2011–2030, the Government aims to increase the share of renewable energy in the country's energy mix. In addition, Côte d'Ivoire committed itself to the Paris Agreement to reduce its greenhouse gas emissions. This commitment is reflected at the level of the electricity sector, by increasing the share of renewable energy in the energy mix to 42 per cent (including large hydropower) by 2030. This renewable energy policy will support the following renewable sources: biomass, hydropower, solar power and, possibly, wind power.

Several projects for electricity generation from renewable energy sources are planned, including: a solar power project of 25 MW in Korhogo; a Canadian solar power project (Galilea) of 50 MW in Korhogo; a solar PV project of 25 MW in Odienné; a solar power project of 25 MW developed by Bio-Therm Energy in Ferkéssedougou; a cocoa biomass power plant of 25 MW in Gagnoa; and a cotton biomass power plant of 20 MW in Boundiali.[21,18,22]

At the end of 2019, the country adopted a Sector Policy Document for the Development of Renewable Energies and Energy Efficiency (PSDEREE) with the vision of making Côte d'Ivoire a leading country in the field of renewable energy, optimal use of energy in all its forms, in order to contribute to the country's energy security and the protection of the environment in 2030.[23] This document has set the objectives of Côte d'Ivoire in terms of renewable energy and energy efficiency for the period 2020-2030. The specific objectives in terms of renewable energy are as follows:

- To promote the development of green electricity production infrastructure connected to the interconnected grid so as to increase the share of renewable energy in the electricity mix to 42 per cent in 2030, including large hydropower;
- To promote the development of green electricity production infrastructure not connected to the interconnected grid in order to accelerate the electrification of camps and isolated sites;
- To increase access to electricity for rural populations through off-grid electrification and to promote renewable energy for other uses, in particular domestic and commercial applications;
- To increase the production and use of fuels from renewable sources other than wood (briquettes, biogas, biofuels, etc.) as well as to promote modern technologies for charcoal production;
- To increase the use by households, hotels, health centres and school canteens of modern cooking systems and solar water heaters;
- To increase access to energy services for farmers through the use of renewable energy in production systems, including irrigation (solar pumping), units for processing and preserving agricultural products, pasteurization, fish farming, etc.;
- To reduce greenhouse gas emissions through the promotion of renewable energy.

There is no specific legislation or regulation for SHP. Data on costs of SHP development are not available. In addition, no financial mechanism is put in place for the development of SHP projects.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Increased variability in rainfall and shifting rainy seasons will require attention if the SHP sector is to adapt to climate change in the future. Rising temperatures are also of concern, and consequences for the sector due to temperature change should be a topic of further attention.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

There are multiple barriers to SHP development in Côte d'Ivoire. Some of the most significant ones are outlined below:

- The lack of new studies on potential sites; new studies could confirm a potential significantly greater than the current estimation of 40.685 MW;
- The main focus is on larger hydropower projects rather than on plants with capacity of up to 10 MW;
- Limited data available in the sector and restriction of information might considerably deter foreign investment.

However, due to the importance of the electricity sector for the country's economic recovery, more attention is being paid to the potential of renewable energy and it is likely that SHP will also benefit from this.[11]

The following points summarize the main enablers that have been identified:

- The political will to accelerate the transition to renewable energy sources including SHP in order to improve the electricity mix, which is predominantly fossil-based (natural gas) at the moment;
- The political will to electrify all the localities of the country by 2025. Although the preferred option is the connection by extension of the electricity grid, the development of local potentials so as to allow a better penetration of renewable sources including SHP, is recommended;
- The country is currently benefiting from technical assistance from the European Union to carry out the necessary studies to enable the development of the potential of renewable energy sources, including SHP.

Republic of the Gambia

Annabel Johnstone, Kaboni

KEY FACTS

Population	2,347,706 (2020)[1]
Area	11,300 km^2 [2]
Topography	The topography of Gambia is flat and largely defined by the drainage basin of the Gambia River. The highest point is in the east of the country, at Red Rock, at 53 metres above sea level. The land elevation gradually decreases from the east to the west, with the capital city of Banjul situated below 5 metres above sea level at the mouth of the Gambia River. Shallow valleys characterize the banks of the Gambia River, which cuts through the plateau across the country.[3,4]
Climate	Gambia has a wet-and-dry tropical climate characterized by an intense rainy season occurring generally between June and October, followed by a longer dry season. The east of the country experiences a hotter and drier climate (temperatures in the high 20s °C), with the climate becoming cooler and drier in the west by the coast (temperatures in the low 20s °C). The relative humidity is high but drops from December to April, when the dry north-eastern wind known as the Harmattan is dominant.[5]
Climate Change	Gambia is highly vulnerable to rainfall variations caused by climate change, which disrupt the agricultural workers' (44 per cent of the population) traditional knowledge of the historic patterns of rainfall and optimal harvest times. Climate change impacts, such as increasing temperatures, droughts, a shifting rainy season with decreased intensity as well as increased deforestation, have resulted in half the available land in Gambia becoming degraded through topsoil and secondary sediment erosion. According to the Climate Change Knowledge Portal, mean annual temperatures are expected to rise by between 1.1 and 3.1 °C by 2060, and between 1.8 and 5 °C by 2090 .[6,7,8]
Rain Pattern	The rainy season lasts longer and is heavier by the coast, while rainfall intensity diminishes eastwards. At the town of Yundum (west), the average annual rainfall averages 1,300 mm, while at the town of Basse Santa Su, approximately 435 km inland, it averages 1,000 mm. August is the rainiest month, when rainfall exceeds 300 mm in the city of Banjul.[4,5]
Hydrology	Gambia is dominated by the Gambia River, a major river of Western Africa. The river, 470 km long, and its tributaries occupy 970 km^2 of permanent surface water area. Total renewable water resource in Gambia is constant at 8x10^9 m^3 per year, of which approximately 62 per cent flows into Gambia from neighbouring countries. The total head of the Gambia River in Gambia is 10 metres. A combination of increased temperatures and reduced rainfall from climate change is expected to decrease annual streamflow by 22 per cent by 2050, according to a global warming scenario of 3.5 °C by the year 2100.[9,10]

ELECTRICITY SECTOR OVERVIEW

The electricity sector in Gambia is predominantly non-renewable, with only 3 MW of the 105 MW of installed capacity as of 2019 coming from renewable sources (2 MW of solar power and 1 MW of wind power) (Figure 1). Similarly, most new capacity added over the last decade comes from non-renewable sources: 11 MW from non-renewable sources compared to 2 MW from solar power.[11]

Gambia does not import or export electricity. However, projects from the World Bank, United Nations Environment Programme (UNEP) and the Economic Community of West African States (ECOWAS) have proposed the development of the Soma hydropower plant in neighbouring Senegal as a shared project, which would represent a supply increase for Gambia to approximately 250 MW.[12,13]

Figure 1. **Installed Electricity Capacity by Source in Gambia in 2019 (MW)**

Source: IRENA[11]

Total electricity generation reached 342.6 GWh in 2019, 336.1 GWh of which came from fossil fuel sources, with only 6.5 GWh of electricity generated from solar power and no recorded wind generation (Figure 2).[14]

Figure 2. **Annual Electricity Generation by Source in Gambia in 2019 (GWh)**

Source: Africa Energy Portal[14]

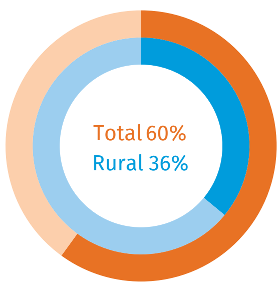
Until 2007, the country's electricity sector was controlled by the National Water and Electric Company (NAWEC), a vertically integrated monopoly under the supervision of the Ministry of Petroleum and Energy. In 2007, the Global Electric Group (GEG) was contracted by NAWEC to build, own, operate and maintain one of the two heavy fuel oil power generation facilities in the greater Banjul area in Brikama Kabafita, known as the Brikama power plant. This nearly doubled the available capacity in the country from approximately 31 MW to 55 MW. The GEG now jointly handles operations with NAWEC. Although this agreement set the precedent for the use of the independent power producer (IPP) structure in Gambia, no new electricity generation capacity has been added since, despite interest from other potential IPPs. Organisations responsible for encouraging investment in the country are the Renewable Energy Association of the Gambia (REAGAM) and the Gambia Investment and Export Promotion Agency (GIEPA).[15]

Special attention can be paid to REAGAM, a non-profit cooperation of approximately 17–19 private and public companies and individuals active in the promotion of renewable energy projects in the country, such as small solar photovoltaic (PV) installations, solar thermal power and micro-hydropower.

Despite the current low share of renewable sources in its energy mix, Gambia has a target to achieve a 100 per cent renewable energy mix by 2050, with 20 per cent of electricity coming from renewable sources by 2030. [11]

In 2018, 60 per cent of the total population had access to electricity, including 76 per cent of urban residents and 36 per cent of rural residents (Figure 3).[14]

Figure 3. **Electrification Rates in Gambia in 2018 (%)**



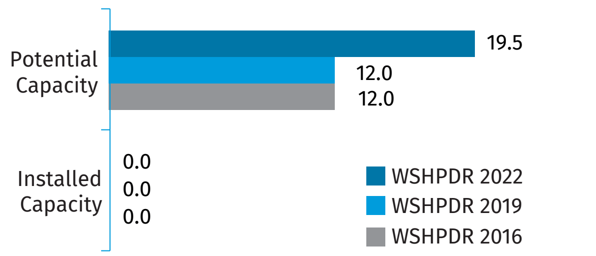
Source: Africa Energy Portal[14]

The regulation of electricity tariffs is the key role of the Public Utilities Regulatory Authority (PURA), alongside monitoring and enforcing standards of performance by public utilities and protecting the interests of the consumers. Electricity tariffs are regulated at 0.26 USD/kWh for the highest domestic consumption band and remain vulnerable to oil prices and foreign exchange shocks.[15] A lifeline tariff is offered for low-income households for the first 40 kWh consumed at a subsidized rate of 0.07 USD/kWh.[15]

SMALL HYDROPOWER SECTOR OVERVIEW

Small hydropower (SHP) is defined as hydropower plants with a capacity of up to 30 MW. For the purposes of this chapter, SHP will refer to hydropower plants with an installed capacity of up to 10 MW. Compared to the World Small Hydropower Development Report (WSHPDR) 2019, the SHP sector of Gambia has not seen any development. The estimate of technical potential for SHP up to 10 MW increased by 7.5 MW, to 19.5 MW, due to access to more accurate data (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2016/2019/2022 in Gambia (MW)**



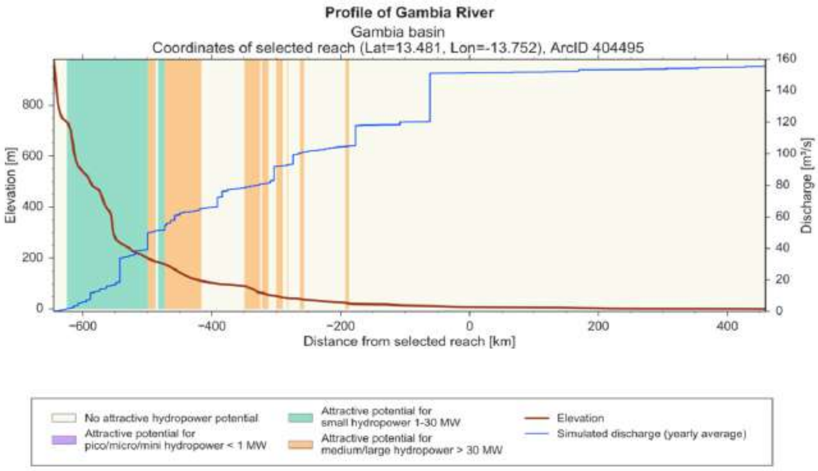
Source: *WSHPDR 2016*,[16] *WSHPDR 2019*,[17] Korkovelos et al. 2018[18]

Note: Data for SHP up to 10 MW.

There are currently no active or planned hydropower plants in Gambia, although there is a planned Western African project under ECOWAS supervision with implications for Gambia. The project envisions that two new hydropower plants located in close proximity to one another will be connected to a new regional network. The plant at Kaléta (240 MW) along with the Souapiti hydropower plant (450 MW) in Guinea will be connected to the mining region of Boké, Sénégal, Guinea Bissau and Gambia through the OMVG (the Gambia River Development Organization) line and to Côte d'Ivoire, Liberia and Sierra Leone through the CLSG (Côte d'Ivoire, Liberia, Sierra Leone and Guinea) line. The Sambangalou plant (128 MW) in Senegal will further connect to the capital of Gambia, Banjul.[19,20]

The lack of activity in SHP development in Gambia can be explained by the limited hydropower potential. In 2017, Pöyry in conjunction with ECOWAS and the ECOWAS Centre for Renewable Energy and Energy Efficiency (ECREEE) undertook a project of mapping SHP development potential in 14 Western-African countries.[21] The report found that Gambia was well suited for SHP development, with the theoretical

Figure 5. **The Level of Attractiveness of Small Hydropower in Gambia by Elevation (m) and Discharge (m³/s)**



Source: ECREEE[14]

hydropower potential for the Gambia River estimated at 10 MW (reference period 1998–2014), whereas the estimated potential of other small streams is negligible. Therefore, all of the identified potential hydropower sites in Gambia are suitable for SHP development.[22]

The attractiveness of any hydropower projects on the Gambia River drops off at the elevation of 25 metres (Figure 5) and as mentioned previously, the entire hydrology system in Gambia has a maximum head of only 10 metres.[14]
A separate study conducted in 2018 found only one potential mini-hydropower site (0.1–1 MW) with 0.5 MW of potential capacity and three potential SHP sites (1.01–10 MW) totalling 19 MW. However, the locations of these sites are unknown.[20] Therefore, the known technical potential of SHP in Gambia is 19.5 MW, coming from four sites.

RENEWABLE ENERGY POLICY

The passing of the Renewable Energy Act in 2013 was a major step forward for Gambia in terms of the promotion of renewable energy. The Act defines a number of functions for the Ministry of Energy, including:

- Recommending national renewable energy targets;
- Determining equipment eligible for tax exemption;
- Preparing and co-ordinating the permitting process for facilities using renewable energy sources;
- Promoting the implementation of educational programmes within the renewable energy sector;
- Encouraging the development of technical and standard requirements and certification of renewable energy plants; and
- Establishing and managing a registry to monitor renewable energy facilities.[23]

The Act also defines a number of functions for PURA, including:

- Managing the Renewable Energy Fund;
- Maintaining a register of installers of systems using renewable energy resources; and
- Requiring importers of systems using renewable energy resources to provide details of compliance with internationally recognized performance and safety standards.

The Act establishes the Renewable Energy Fund and defines its funding sources, activities to be funded and management structure. The Act allows for feed-in tariffs (FITs) for on-grid renewable electricity projects with a capacity up to 1.5 MW. The maximum national capacity limit for electricity production eligible under the Act is to be published in the Feed-in Tariff Rules. The Act also provides clarification about off-grid tariffs. Renewable energy or hybrid off-grid plants of no greater than 200 kW are allowed to charge electricity tariffs to end consumers up to the current national retail tariff rates. For systems of greater than 200 kW and if the power plant developer wants to charge above the national retail tariff rate, developers must justify the tariff to the PURA as per the Electricity Act.[26]

However, certain gaps exist in the Act, which, if addressed, would provide key information for potential renewable energy development. These gaps consist of, but are not limited to:

- Provision of FITs for on-grid renewable energy plants of more than 1.5 MW;
- Provision of tariffs for off-grid renewable energy plants of more than 200 kW;
- Technical and standard requirements and certification of renewable energy plants.

There is no specific mention of SHP in the Renewable Energy Act, apart from as part of hybrid power plants. As such, the process for SHP projects should not be determined as different to the licence pathways for other renewable generation projects, which was streamlined under the Act. Instead, the Act specifically mentions biomass as a main strategy towards electrification.

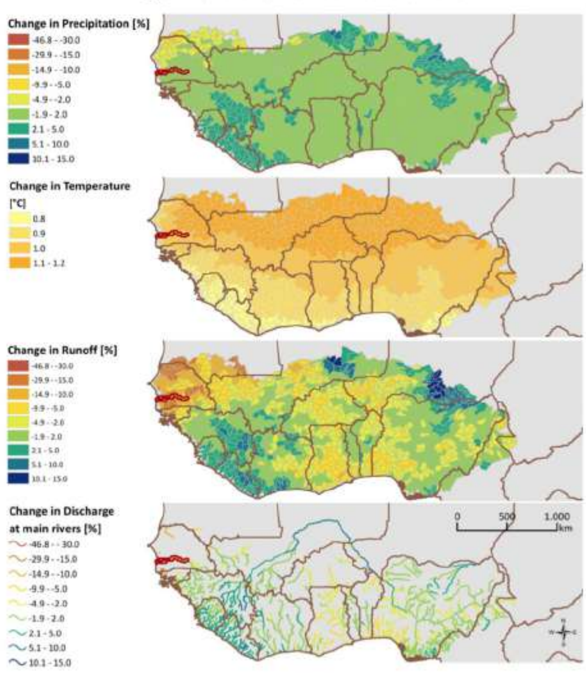
FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

Grid-connected SHP would be eligible for partial financing in the Nationally Appropriate Mitigation Action (NAMA) report of the Renewable Energy Fund set up in 2013, as well as VAT exemptions on electricity produced. There are also opportunities to attain grant financing from ECOWAS, though the pathways are unclear. The World Bank has an ongoing project to restore and modernize the electricity system in Gambia, though references in the concept note to hydropower are uncommon and more emphasis is put on solar power projects for off-grid and rural electrification.[25] The project was approved in 2018 and received additional financing in 2020.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Climate change may have considerable impact on future water resources and therefore hydropower generation. Figure 6 shows an assessment of climate change projections for Western Africa based on 15 regional climate models of the CORDEX-Africa ensembles. Two Representative Concentration Pathways (RCP4.5 and RCP8.5) were considered.[22] Whilst these changes have direct impacts on technical specifications of SHP, they will also have indirect impacts on the national tariff, reduction in agricultural revenue and an increase in flooding emergency if no immediate mitigation measures are taken.

Figure 7. **Change in Precipitation, Temperature, Runoff and Discharge in Western Africa under RCP4.5 and RCP8.5**



Source: ECREEE[21]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The electricity sector of Gambia is characterized by a number of enablers which provide opportunities for the realization of the goal of universal access to electricity. The strengths of the power sector, which could foster SHP development include the following:

- The Government's strong commitment to expand the electricity network to many communities in the country;
- Willingness of the private sector (investors) to partner with the Government to provide electricity services;
- Examples of connectivity within the subregion to learn from;
- Availability of financing through the FIT scheme;
- Available information on potential SHP sites for future development;
- Presence of a market (domestic and commercial) for the electricity that could be produced in future.

The electricity sector also faces several challenges in achieving the stated goal of ensuring wider access to electricity in Gambia, which complicates SHP development in the country. The sector barriers include the following:

- Inadequacy of the transmission and distribution network, creating incompatibility for large-scale public-private partnerships;
- Operational inefficiencies in the key utility company NAWEC resulting in transmission and distribution losses;
- NAWEC's poor financial performance;
- Weak regulatory and enforcement capacity;
- High electricity tariffs and non-affordability of electricity;
- Limited SHP potential in the country.[15,26]

These challenges combined with the low availability of commercially attractive sites will make any new development of SHP in Gambia challenging. The most viable area to focus on with SHP is the Gambia River and its estuaries in the centre of the country, near the village of Tendaba.

Ghana

Chinedum Ibegbulam, Renewable Energy and Development Practitioner

KEY FACTS

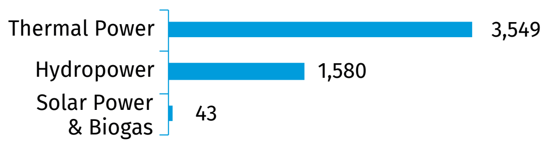
Population	31,498,920 (2022)[1]
Area	238,540 km^2 [2]
Topography	The physical terrain of Ghana is primarily represented by low plains, with several uplands and a major plateau in the south-central region. The country's highest point is Mount Afadjato at 885 metres above sea level.[3]
Climate	Ghana is characterized by a tropical climate that is relatively mild for the latitude. With the exception of the north, two rainy seasons exist, which run from April to June and from September to November. There is also a harmattan season, which is characterized by dry wind blowing from the north-east from December to March. Average temperatures range between 21 °C and 32 °C. In most areas, temperatures are highest in March and lowest in August, but no temperature lower than 10 °C has ever been recorded in Ghana.[4]
Climate Change	Over the 1961–2000 observation period, a progressive rise in temperatures and a decrease in mean annual rainfall have been recorded across the country. Other observed effects of climate change include increased variability of precipitation, rising sea levels and high incidence of extreme weather conditions and disasters. In the last 30 years, the average annual temperature increased 1°C and is projected to continue to rise. Similarly, rainfall is predicted to continue to decrease.[5]
Rain Pattern	There is a significant variation of rainfall pattern throughout the country. In the south, annual precipitation averages 2,030 mm, while Axim in the south-west of the country has the heaviest rainfall. Averagely, the month of June is the wettest month with rainfall of approximately 225–250 mm.[6]
Hydrology	Most rivers and streams north of the Akuapim-Togo ranges, including Black Volta and White Volta, form part of the Volta River system. The Volta River is approximately 1,600 kilometres in length and drains an area of approximately 388,000 km^2. The Black Volta and White Volta meet at Lake Volta, which was formed as a result of the construction of the Akosombo dam. It is also the world's largest man-made lake. There are also several other smaller rivers such as Pra, Tano, Densu, Birim and Densu.[6]

ELECTRICITY SECTOR OVERVIEW

In 2019, Ghana had a total installed generation capacity of 5,172 MW (4,695 MW of available capacity), which comprised 3,549 MW (3,296 MW available) from thermal power plants, 1,580 MW (1,365 MW available) from hydropower plants and 42.6 MW (34 MW available) from solar power and biogas combined (Figure 1).[7] The electricity generation mix in Ghana has primarily relied on hydropower and thermal power sources, however, steps have been made to introduce other renewable energy technologies in order to diversify the mix. In 2019, solar power and biogas accounted for 0.8 per cent of total installed capacity, indicating an increase compared to 0.2 per cent in 2016.[8]

Electricity generation in 2019 totalled 18,189 GWh, with thermal plants contributing almost 60 per cent (10,885 GWh), hydropower plants 40 per cent (7,252 GWh) and solar power and biogas combined 0.3 per cent (52 GWh) (Figure 2).[7] An additional 127 GWh was imported into Ghana in 2019 and 1,430 GWh was exported, making the net export 1,227 GWh.[7] Ghana imports electricity from Côte d'Ivoire and exports electricity to other neighbouring countries, including Benin, Togo and Burkina Faso. The ongoing grid expansion will allow for further expansion to other neighbouring Sub-Saharan African countries.

Figure 1. **Installed Electricity Capacity by Source in Ghana in 2019 (MW)**



Source: Energy Commission[7]

Figure 2. **Annual Electricity Generation by Source in Ghana in 2019 (GWh)**

Source: Energy Commission[7]

The National Electrification Scheme (NES) served as the principal instrument towards providing universal access in Ghana over a 30-year period (from 1990 to 2020). Since 1990, there has been a trend of annual increase in electrification access rate of 2.6 per cent.[9] However, the set electrification target was not achieved and in 2020 the national electrification rate stood at 86 per cent, including 95 per cent in urban areas and 74 per cent in rural areas.[10]

Before the late 1990s, the electricity sector of Ghana was a vertically integrated monopoly, with the Volta River Authority (VRA) responsible for generating and transmitting electricity to every region of the country as well as its distribution in the Northern Region through its subsidiary the Northern Energy Department (NED). The electricity sector reform in the late 1990s split the VRA and provided an opportunity for independent power producers (IPP) to enter the market. Electricity generated from hydropower is controlled by the VRA and Bui Power Authority (BPA). Additionally, the VRA and IPPs are also involved in some aspects of thermal power generation. Transmission is solely controlled by Ghana Grid Company (GRIDCO), while distribution is controlled by the state-owned entities the Electricity Company of Ghana (ECG) and the Northern Electricity Distribution Company (NEDCO).[11]

The Ministry of Energy is in charge of the formation, monitoring and evaluation of polices, programmes and projects for the country's electricity sector and is also responsible for the implementation of the NES. There are two regulatory entities responsible for the electricity sector in Ghana. The Energy Commission (EC) is responsible for issuing generation licences and for formulating electricity policy and rules governing the electricity sector including a grid code. The Public Utilities Regulatory Commission (PURC) is responsible for the regulation of the electricity, gas and water sectors, which includes tariff setting.[9]

The regional stakeholders, such as the West African Power Pool (WAPP), the ECOWAS Regional Electricity Regulatory Authority (ERERA) and ECOWAS Centre for Renewable Energy and Energy Efficiency (ECREEE), play an important role in the improvement of energy security in the country through interstate electricity trade and supporting improved energy services. International agencies providing support to the electricity sector of Ghana, ranging from technical assistance to financing power infrastructure projects, include the World Bank Group, African Development Bank (AfDB), United States Agency for International Development (USAID), Canadian International Development Agency (CIDA), International Renewable Energy Agency (IRENA), United Nations Environment Programme (UNEP) and Global Environment Facility (GEF).[9]

In order to sustain the real value, electricity tariffs in Ghana are adjusting based on a number of factors, such as fuel price, foreign exchange, inflation and generation mix. For low-income consumers with low consumption, PURC instituted the lifeline tariff below the cost of electricity provision.[9] Electricity tariffs are grouped into six categories based on consumer category (residential, non-residential, special load tariff and mines) and voltage level. As of January 2021, the price per kWh of electricity for residential consumers ranged from 0.33 GHS (0.04 USD) to 0.94 GHS (0.12 USD), with a monthly service charge of 7.46 GHS (0.95 USD/month) for regular consumers.[12]

SMALL HYDROPOWER SECTOR OVERVIEW

In Ghana, small hydropower (SHP) is defined as hydropower plants with capacity of up to 1 MW. Additionally, medium-scale hydropower is defined as plants with 1–10 MW capacity and large-scale hydropower as plants with 10–100 MW capacity.[13]

At present, there is one installed SHP plant in Ghana, which is the Tsatsadu power plant located in Alavanyo, Volta region. The plant was launched in 2020 and has an installed capacity of 45 kW (Table 1).[14] The SHP potential up to 10 MW is estimated to be at least 17.42 MW and approximately 9.9 MW for SHP up to 1 MW.[13] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, installed capacity increased due to the commissioning of a new plant and potential remained unchanged (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Ghana (MW)**

Tsatsadu	Alavanyo, Volta region	0.045	Run-of-river	Bui Power Authority (BPA)	2020

Source: Bui Power[14]

According to a 2012 report, the hydropower potential capacity in Ghana is 2,420 MW.[13] Various studies provide different estimates of SHP potential in different regions of the country. The Hydrological Service Department of the Ministry of Works and Housing identified approximately 15.18 MW of SHP potential from 69 sites below 2 MW. Additionally, reports by the Energy Foundation suggest that there is a potential for 2.24 MW from 12 sites less than 1 MW. Therefore, it can be assumed that the total SHP potential up to 10 MW in Ghana is at least 17.42 MW.[13] Table 2 shows a list of selected most interesting potential SHP sites identified using topographic sheets and flow data from several rivers.

Table 2. **List of Selected Potential Small Hydropower Sites in Ghana**

Name	*Location*	*Capacity (MW)*	*Head (m)*	*Plant type*	*Type of site (new/refurbished)*
Wli Falls	Afegame, Volta region	0.30	250	Run-of-river	New
Likpe Kukurantumi	Likpe Kukurantumi, Volta region	0.10–0.15	Up to 5 m by dam	Reservoir	Refurbished (construction went on for 11 months before work stopped)
Kokuma Falls	Kokuma, Brong-Ahafo	0.05	23	Run-of-river	New
Randall Falls	Kintampo, Brong-Ahafo	0.08	40	Run-of-river	New
Nworannae Falls	Asmpanaye, Western region	0.04	50–100	Run-of-river	New

RENEWABLE ENERGY POLICY

Ghana heavily depends on hydropower, mainly from the Akosombo dam, as a source for electricity generation, because hydropower provides the cheapest source of electricity compared to thermal power and other renewable energy sources. Nonetheless, the potential for alternative sources of electricity exists in the country, which includes medium-sized hydropower, mini-hydropower and other renewable energy sources, such as solar and wind power.

In 2011, the Renewable Energy Act (Act 832) was passed in order to provide a legal framework for renewable energy development.[18] The key provisions of the act included a feed-in tariff (FIT) scheme, purchase obligation and net metering. As a result, EC together with PURC developed a FIT to incentivize investment in the sector. PURC is mandated to set the FIT rates, based on which developers would be able to sign power purchase agreements (PPAs) with the distribution companies following a written approval from PURC. The Renewable Energy Act also provides for the establishment of a Renewable Energy Fund, which provides financial resources for renewable energy projects.

The Renewable Energy Master Plan (REMP) developed in 2019 offered a roadmap for long-term development of renewable energy in the country until 2030. The REMP set the following targets to be achieved:

- Increase the installed capacity of renewable energy (including hydropower up to 100 MW) to 1,363.63 MW;
- Reduce dependence on biomass;
- Provide decentralized renewable energy-based electrification options in 1,000 off-grid communities;
- Promote local content and participation in the renewable energy industry.[19]

The REMP also prescribed action plans for all renewable energy technologies. For hydropower (small- and medium-scale), the 2030 installed capacity target is set at 150 MW. According to the REMP, the Government aims to develop multiple SHP plants. The Tsatsadu plant was the first project developed under the plan. The key strategies for promoting hydropower include:

- Fast track and deploy innovative financing instruments;
- Develop a clear framework and legislation for small- and medium-scale hydropower development;
- Provide incentives, such as state-funded feasibility studies and public-private partnership arrangements;
- Collaborate with relevant stakeholders to create buffer zones, undertake reforestation and prevent mining, farming and logging activities along water ways;
- Encourage hybrid and multipurpose hydropower development (fisheries, transportation, irrigation, etc.);
- Provide capacity building for utilities, local authorities and research institutions in the installation, operation and maintenance of hydropower facilities.[19]

The Volta River Development Act 1961 (Act 46) (the VRA Act) established the oldest power entity in Ghana, the VRA. The VRA Act tasked the VRA with the responsibility to generate electricity by means of hydropower on the Volta River. In 2007, the Parliament enacted the Bui Power Authority Act 2007 (Act 740) (the Bui Power Act), which established the Bui Power Authority to oversee the development of the Bui hydropower project and any other potential hydropower sites on the Black Volta River.[20]

Under the Energy Commission Act 1997 (Act 541), participation in any segment of the electricity sector requires a licence. EC is required to make a decision on any application within a maximum period of 16 days. Reasons for denying licence issue can be founded on technical data, national security concerns, public safety or any other reasonable justification. The VRA is exempted from the requirement to apply for a licence for producing and supplying wholesale electricity from hydropower plants in the Volta River basin. Furthermore, under the Renewable Energy Act, every entity intending to engage in a commercial activity in the renewable energy sector requires a licence. To construct and operate distribution networks, an electricity distribution licence issued by EC is required. An electricity distribution licence is site-specific.[20]

In 1994, the Environmental Protection Agency Act 1994 (Act 490) was enacted in order to ensure that electricity is produced, transmitted and distributed in an environmentally sustainable manner. The act established the Environmental Protection Agency (EPA) as the principal environmental regulator in the country. Before undertaking a project, an electricity utility must receive an environmental permit from the EPA. The EPA ensures compliance with the environmental impact assessment (EIA) procedures.[20]

COST OF SMALL HYDROPOWER DEVELOPMENT

A 150 kW site at Likpe Kukurantumi with an annual output of 500–640 MWh was suggested for development. The construction cost was estimated at USD 300,000, or USD 2,000 per kW installed. The site has a head of 5 metres and, given that low-head sites are relatively more expensive to construct than high-head sites, the actual cost could be higher at approximately 3,500 USD/kW.[21]

FINANCIAL MECHANISM FOR SMALL HYDROPOWER PROJECTS

Existing financial mechanisms available for SHP projects include internally generated revenue, bilateral financing and financing from international and non-governmental organizations as well as foreign governments. The Tsatsadu SHP plant was funded largely by the Government of Ghana through BPA with financial support from the Government of Denmark and the United Nations Development Programme (UNDP).[14] An example of bilateral financing is the 400 MW Bui Dam hydropower project financed through a concessional loan of USD 270 million and a commercial loan of USD 292 million offered by China Ex-Im bank and USD 60 million in funding from the Government of Ghana.[22]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The climate crisis poses risks to SHP development in Ghana primarily through changes in precipitation, including decreased rainfall and increased variability, and higher incidence of extreme weather conditions. A range of tailored adaptation measures based on a systematic assessment of climate risks will be required to ensure sustainable operation of SHP plants, including the physical enhancement of assets and development of appropriate strategies and policies related to, for example, emergency response and recovery.[23]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Barriers to SHP development in Ghana include:

- Lack of a regulatory and legal framework for SHP development;
- Limited funding opportunities;
- Minimal national and regional knowledge and awareness of the potential of SHP;
- Limited local expertise in developing SHP projects;
- Lack of data on water availability and flow for the development of SHP;
- Impacts of climate change on hydropower generation.[17,24]

Nonetheless, further SHP development in Ghana is possible due to the following factors:

- Political will to develop renewable energy and increase electricity access, with specific goals set for hydropower;
- Availability of undeveloped potential, with a number of suitable sites identified;
- Availability of international and regional support for renewable energy development in the country.

KEY FACTS

Population	12,907,395 (2021)[1]
Area	245,857 km^2 [1]
Topography	The mid-northern region of Guinea extends from east to west in the form of a maritime plane (Lower Guinea), a region of plateaus and mountains (Middle Guinea) and the arid plateau of Upper Guinea. The south-western tip of the country, in the interior of the continent is a forested mountainous region known as Forested Guinea. It is here that the country's highest point, Mount Nimba (1,752 metres), is located. Middle Guinea surrounds the Fouta Djalon Massif, which covers an area of approximately 80,000 km^2 and culminates at Mount Loura (1,532 metres). It is mainly made up of plateaus, often more than 1,000 metres high, cut by valleys, dominating plains and depressions up to approximately 750 metres. The coastal plain of Lower Guinea is dominated to the east by the Benna Massif (1,214 metres), Mount Kakoulima (1,011 metres) and Mount Gangan (1,117 metres).[2]
Climate	The climate of Guinea is tropical or sub-equatorial depending on the area. The diversity of the terrain divides the territory into four regions with distinct climatic conditions. Lower Guinea has the longest rainy season of six months and temperatures range from 23 °C to 25 °C. Middle Guinea has shorter rainy seasons compared to Lower Guinea. In Upper Guinea, the climate is tropical and dry, with only three months of a rainy season and temperatures reaching at most 40 °C in the north-east and lows reaching 15 °C in the winter months. Forested Guinea has an equatorial climate with two separate rainy seasons interrupted by a short dry period. This region is largely humid with temperatures fluctuating between 24 °C and 28 °C for the most part of the year.[3,4]
Climate Change	According to global circulation models, annual rainfall variability and temperatures are expected to increase in Guinea under all scenarios, with some regional variation. Under a global warming scenario of 4.5 °C, the range of temperature increase in the country is expected to be between 0.4 °C and 4.8 °C by 2100. Under the 1.5 °C global warming scenario, temperatures will increase by 0.2-2.2 °C.[2]
Rain Pattern	Precipitation in the country varies by region. In the north, annual precipitation is approximately 1,200 mm per year, whereas in the south, precipitation levels can reach as high as 4,000 mm per year. Although the average in the south-east is between 1,700 and 3,000 per year. The central mountainous region of Middle Guinea has precipitation levels ranging from 1,500 to 1,300 mm per year, with the rainiest season being from April to October and the dry season from November to March.[4]
Hydrology	Nearly 1,161 water bodies in the country are fed by two mountainous massifs: the Fouta-Djallon and the Guinean Highlands (Dorsale Guinéenne). Most of the rivers have a regular flow because of the high rainfall and the very flat topography of the coastal region. However, in the part of the Lower Guinea region that borders the Fouta Djallon in its foothills, the rivers sometimes have a torrential flow due to the steepness of the slope and the rocky bottom. The most important rivers are: the Coliba, Kogon, Tinguilinta, Fatala, Konkouré, Soumba, Kolenté, and Forécariah. The prominent rivers in Middle Guinea are the Bafing and Gambia. The main rivers in Upper Guinea are the Bafing, Bakoye and the Niger basin, whose main tributaries are Mafou, Niandan, Milo, Tinkisso, Dion, Sankarani and Fié. Together they total approximately 2,500 kilometres of waterways. In addition, there are numerous large ponds and flood plains that run alongside the rivers, covering an average area of 2–4 km^2. In Forested Guinea, the main bodies of water and watercourses are made up of numerous very small ponds of less than 1 hectare in size.[2,5]

ELECTRICITY SECTOR OVERVIEW

Apart from small-scale, off-grid generation, the electricity demand of Guinea is largely met by two sources: hydropower and thermal power. Total installed capacity as of 2019 was 601.9 MW. Hydropower made up most of the installed capacity at 362.1 MW, thermal power accounted for 226.8 MW and solar power accounted for 13 MW (Figure 1).[6,7]

Figure 1. **Installed Electricity Capacity by Source in Guinea in 2019 (MW)**

Source: EDG,[6] IRENA[7]

Note: Data only for the interconnected electricity grid (RIC).

In 2019, electricity generation in Guinea was equal to 2,040.7 GWh, of which 1,279.6 GWh came from hydropower, 21 GWh from solar and 740.1 GWh came from thermal power plants (Figure 2).[7,8] Hydropower made up 63 per cent of the on-grid generation. Of the electricity produced in 2019, the electricity company Electricité de Guinée (EDG) produced 25 per cent (496.1 GWh), while the remaining 1,483.4 GWh was produced by independent power producers (IPPs). The majority of hydropower generation is from the private Kaleta generator, which peaks in production from July to November, making up most of the country's electricity supply during these months.

Figure 2. **Annual Electricity Generation by Source in Guinea in 2019 (GWh)**

Source: EDG,[8] IRENA[7]

Note: Data only for the interconnected electricity grid (RIC).

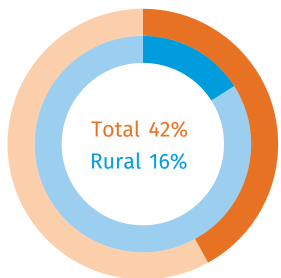
The electricity sector covers 26 urban centres in the prefectures whose electricity networks are managed and operated by EDG. EDG is charged with ensuring the provision and transport of electricity throughout the country and owns 35 per cent of the electricity market, acting as the sole buyer for many electricity producers. The Ministry of Energy (ME) (previously Ministry of Energy and Hydraulics (MEH)) oversees the electricity sector. Its organization and prerogatives were defined by Decree No. D/2016/122/PRG/SGG of 2016. Article 1 of this decree provides that the Ministry's mission is the design, development and implementation of the Government's water and energy policy. A presidential decree in 2005 established the Office of Strategy and Development of Energy (BSD), an organization charged with elaborating a strategy for the development of the energy sector. The Cellule PPP manages the public-private partnerships within the Government and acts as an interface for IPPs in the country. The country's independent power regulator, AREE (Authority for Electricity and Drinking Water Sectors), was created in 2017 by the ordinance L/2017/050/AN.

The main electricity grid, called the large interconnected grid, supplies hydropower and thermal power to Conakry, Dubréka, Coyah, Forécaréah, Kindia, Mamou, Pita, Labé and Fria. The small interconnected grid supplies the prefectures of Dabola, Dinguiraye and Faranah with electricity from the Tinkisso hydropower plant (1.6 MW). There are also the so-called isolated centres (Boffa, Gaoual, Télémelé, Lélouma, Kissidougou, Kouroussa, Boké, Kankan, Kérouané, Macenta and N'Zérékoré), which are supplied with electricity by small-scale generators (often hybrid solar with battery and diesel). A number of mini-grids are operating under concession agreements or authorizations granted by the minister in charge of energy.[9]

The country's ambition is to sell the excess of its future electricity production to neighbouring countries. In addition, Guinea is a member of several subregional organizations such as the Gambia River Basin Development Organization (OMVG) and Senegal River Basin Development Organization (OMVS), which currently work together to develop shared hydropower sites on the territory of Guinea and for the implementation of transmission lines (the Côte d'Ivoire-Liberia-Sierra Leone-Guinea (CLSG) and Guinea-Mali interconnections).[10]

Although endowed with mineral and energy resources, the electricity sector of Guinea remains poorly developed. One of the objectives of the Development of the Energy Sector Policy (Lettre de Politique de Développement du Secteur Energétique, LPDSE) of December 2012 is to increase the global electrification rate from 12 per cent in 2014 to 50 per cent by 2020.[11] While significant progress has been made since 2014, the goal for 2020 has not yet been met. As of 2019, 58 per cent of the Guinean population remained without access to electricity (Figure 3).[12] The likelihood of rural access to electricity being provided by the national grid in the medium to long term is limited, while mini-grids are a cost-effective way to fill this gap in the interim.

Figure 3. **Electrification Rate in Guinea in 2019 (%)**



Source: World Bank[12]

The Government has developed a National Economic and Social Development Plan (PNDES) 2016–2020 that prioritizes renewable energy through decentralized solutions with the participation of the private sector.[13] The strategic purpose of the PNDES is to concretize the LPDSE as well as its Action Plan 2009–2025 to promote the development of a sustainable model based mainly on energy efficiency and renewable energy. Actions of the PNDES involve the promotion of decentralized solutions involving local authorities and the private sector at the rural level. This is in line with the Electricity Access Improvement Programme (2014) and the

Low-Cost Electrification Plan (2019). As for the electrification plans, the Government's strategy is to reach a large portion of the population with the extension of mini-grids.

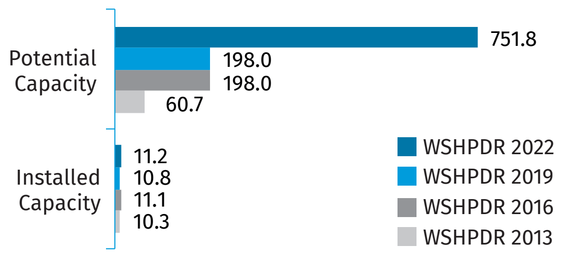
The green mini-grid programme, with support from the African Development Bank, will provide technical assistance to Guinea Agency for Rural Electrification (AGER), in the form of a help desk, for the deployment of 47 green mini-grids that have no prospect of being connected to the national grid in the next 10 years and that should allow the connection of approximately 60,000 households.[14]

The average price for electricity in 2019 was 0.064 USD/kWh (628 GNF/kWh), which indicates a 13 per cent decrease compared to average prices in 2018.[6]

SMALL HYDROPOWER SECTOR OVERVIEW

According to LPDSE, paragraph 23, micro-hydropower is defined as sites with installed capacity from 100 kW to 1,500 kW, whereas small hydropower (SHP) is not clearly defined.[15] For the purpose of this chapter, the up to 10 MW definition will be used. The total installed SHP capacity is 11.2 MW (Table 1), and has not meaningfully changed since the *World Small Hydropower Development Report (WSHPDR) 2019* (Figure 4). At the time of writing, the Banéah (5.6 MW) and Samankoun (0.24 MW) plants were undergoing renovation works, both not being connected to the central electricity grid (Table 1). Theoretical potential for hydropower plants under 10 MW amounts to 751.8 MW, revealing an increase of 280 per cent since the *WSHPDR 2019* due to new data from multiple studies.[16]

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Guinea (MW)**



Source: EDG,[6] SIG,[16] *WSHPDR 2013*,[17] *WSHPDR 2016*,[18] *WSHPDR 2019*[19]

Note: Data for SHP up to 10 MW.

The French Development Agency (ADF) has agreed to co-finance four small dams: Fôkô (2.5 MW, multipurpose, Maritime Guinea), Bagata (2.2-5 MW, Middle Guinea towards Tougué), Founkeya Banko (4-5 MW, towards Dabola, Upper Guinea) and Lokoua (6-13 MW, Forest Guinea) (Table 2). These projects were undergoing technical and financial feasibility studies as of mid-2021.

Table 1. **List of Installed Small Hydropower Plants in Guinea**

Name	*Location*	*Capacity (MW)*	*Operator*	*Launch year*
Banéah*	Kindia	5.60	EDG	1989
Kinkon	Pita	3.44	EDG	1974

Source: SIG[16]

The Atlas of Potential Hydropower in Guinea was put together by AECOM engineering firm, which compiled data from existing studies, such as Tractabel Engineering, and compared these findings with their own.[16] Several sites were then verified and further studied through site visits during the second stage of the process. This report identified new sites using advanced geographic modelling techniques and is the most up-to-date source for potential sites in Guinea as of mid-2021. Despite the identified vast potential of over 6,000 MW only 6 per cent of total known hydropower potential, large and small, has been developed.[16]

Several potential sites of larger capacities have encountered difficulties within the development process. The main causes of failure in hydropower development are: failure in creditworthiness in entering into a Power Purchase Agreement with EDG (as is the case with the Touba plant); change of the mining code leading to increased and complex costs (as is the case with Poudalde, 50–90 MW); and Build Operate Transfer (BOT) schemes, which encounter political problems and competing uses for the site of interest (as with the Fomi plant, 90 MW).

RENEWABLE ENERGY POLICY

The main objective, following the Energy for All initiative, is to increase the share of renewable energy sources in the country's energy mix to 30 per cent.[11] On the national policy level, the LPDSE outlined the following objectives:

- To reach a share of hydropower capacity in the grid electricity (excluding self-generation) of 70 per cent in 2017 compared to 38 per cent after the installation of 100 MW of emergency thermal power capacity in 2013;
- Develop 20 mini-hydropower plants of the inventoried 130 by 2025, including 5 by 2017, under PPP or community projects.[15]

Apart from planning, there are several concrete actions taken to further climate goals. Law L/2013/061/CNT authorizes the participation of private sector operators of plants less than or equal to 500 kW in capacity. The tariffs for the supply of electrical energy or electrical services and the conditions for their revision are established on a case-by-case basis in the specifications of the Electrification Authorizations. According to Article 30, Chapter II: Taxation of Title IV: Tariffs and Taxation, the tax regime applicable to companies holding a rural electrification permit is the most favourable regime of the Investment Code.

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

For hydropower, the main policy angle is to prioritize the development of mini- and small-scale sites with respect to large subregional schemes to meet local needs. Ministerial Order A/2013/474/MEEF/CAB of 11 March 11 2013, which adopted the general environmental assessment guide, specifies that hydropower projects below 10 MW must be subject to an impact notice, while those greater than or equal to 10 MW must be subject to a detailed environmental impact assessment (EIA).

The process for attaining a licence for SHP projects is determined when the authorization or the concession is granted by means of orders of the Minister in charge of the electricity sector, following a call for tender procedure or on the basis of unsolicited applications. Law 98/012/AN of 1 June 1988 authorizes the financing, construction, operation, maintenance and transfer of development infrastructures by the private sector using Build-Own-Operate-Transfer (BOOT) contracts.[23]

The promulgation of Law L/93/039/CTRN of 13 September 1993 on the Production, Transport and Distribution of Electricity, limits the role of the state to the definition of: the energy policy and its instruments (price and tariff system; institutional, legal and regulatory framework), the monitoring of their application and the exercise of the control of the sector. This law was enacted to ensure the quality and continuity of the public electricity service.[24]

Other pieces of legislation pertaining to the SHP sector include: Law L/2013/061/CNT of 20 September 2013, Article 9 which defines the Rural Electrification Zone (ZER), National Rural Electrification Programme (PNER), Annual Rural Electrification Programme (PAER) and the Local Rural Electrification Initiative Projects (PILER).[25]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

Some subsidies are set aside for small renewable generation under article 27, paragraph 2 of Law L/2013/061/CNT of 20 September 2013 on the rural electrification subsector. This law states that the Council for Rural Electrification must "ensure the implementation of the national policy of rural electrification as well as the proper use of resources and the optimal allocation of subsidies allocated by the Rural Electrification Fund (FER) for the development of sustainable access to electricity in rural areas, under conditions of acceptable technical, economic and financial viability, equity and transparency."[25] Financing is also available under the Programme of Decentralized Electrification (PERD) of the Office of Rural Decentralized Electrification (BERD) with co-financing from the World Bank and the Government of Guinea. This programme aims to conduct prefeasibility studies resulting in 12 locations to be selected for tendering for private investment in hybrid plants. The subsidy is estimated to amount to 60-80 per cent of initial investment costs, and has an expected closing date of December 2023.[26]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

According to studies on the effects of climate change on water systems in Guinea, water bodies will be significantly impacted up until 2100, with more significant effects seen in the second half of the century. The first national communication to the United Nations Framework Convention on Climate Change presented projection results by regions within the country on water flow reductions. Under a 1.5 °C scenario, water flow is expected to decrease by 2-8 per cent (depending on the region) by 2025 and by as much as 20-43 per cent by 2100. Under a 4.5 °C global warming scenario, regional decrease in water flow will reach between 6 and 16 per cent in 2025 and reach a reduction of between 34 and 73 per cent by 2100.[2] Several rivers have experienced negative effects due to flooding in recent years, including the Kankan (2001), Boké (2003) and Gaoual (2005).

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The following points summarize the main barriers to SHP development in Giunea that have been identified:

- Poverty of the population, especially in rural areas, and its impact on purchasing power;
- Financial barriers, such as the low national financing capacity (public and private) and subsequent high dependence on external public and private financing;
- Technological barriers including the huge technological backlog in energy industries and know-how as well as high expenses on technology and know-how transfer;
- Institutional barriers, particularly the lack of good overall governance and control of the development of the energy sector as a whole.

The following points summarize the main enablers for SHP development in the country that have been identified:

- There is a huge potential for SHP in the country and ample, available data on specific sites;
- Strong political motivation for mitigation of the negative effects of climate change;
- Interest in the country and financial aid from development institutions.

Liberia

International Center on Small Hydro Power (ICSHP)

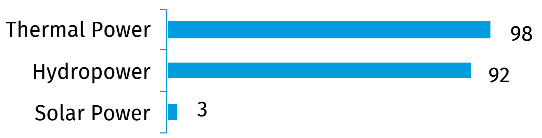
KEY FACTS

Population	5,057,677 (2020)[1]
Area	96,320 km^2 [2]
Topography	The topography of Liberia ranges from flat coastal lowlands to rolling hills and plateaus. Along the border with Guinea runs the Nimba Mountain Range and along the coastal plains are savannahs and degraded forests. The hills of the tropical forest and the montane forest zone are covered by dense rainforests. The highest point in the country, Mount Wuteve, culminates at 1,380 metres above sea level.[3]
Climate	Liberia has a warm and humid climate, especially on the coast. The rainy season lasts from May to October and the dry season from November to April. The dry and dusty desert wind from the Sahara brings relief from the high humidity. Mean annual temperatures in the country range from 18 °C in the northern highlands to 27 °C along the coast.[4]
Climate Change	The key effects of climate change observed in Liberia include droughts and increased temperatures, particularly during summer. An observed increase in heavy rainfall events, erosion and floods threaten many areas of economic and social life in the country. Between 1960 and 2006, mean annual temperature increased by 0.8 °C at an average rate of 0.18 °C per decade. This trend is projected to increase to 0.9 °C for the decades 2020-2039. The average number of hot nights has been increasing as well, with a reported increase of 57 nights. Concomitantly, the average number of cold nights has decreased by 18 days.[5]
Rain Pattern	Average annual rainfall in Liberia exceeds 2,500 mm. Rainfall is high along the coast but decreases towards the plateaus and low mountains. The southern areas receive more rainfall than the rest of the country with the area around Cape Mount receiving the most rainfall (5,200 mm).[4,6]
Hydrology	The Morro and Mano Rivers in the north-west and the Cavalla in the east and south-east of the country are the major rivers in Liberia forming sections of its borders. River traffic and short-distance navigation in most rivers are hindered by rapids, waterfalls and sandbanks that occur often in upstream sections of rivers. The Farmington River is a source of hydropower in the country.[4]

ELECTRICITY SECTOR OVERVIEW

The main sources of electricity in Liberia are hydropower and thermal power. In 2019, total electricity generation in the country amounted to 226 GWh, of which hydropower accounted for 55 per cent and thermal power for 43 per. Solar power accounted for 4 GWh, or 2 per cent, of the total generation (Figure 1).[7]

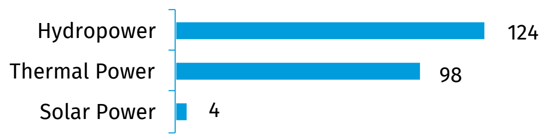
Figure 1. **Annual Electricity Generation by Source in Liberia in 2019 (GWh)**



Source: IRENA[7]

In 2020, the total installed electricity capacity in Liberia was 193 MW, of which thermal power, hydropower and solar power represented 51 per cent, 48 per cent and 1 per cent, respectively. The thermal power accounted for is non-renewable and amounts to 98 MW, whereas the hydropower capacity stands at 92 MW (Figure 2).[7]

Figure 2. **Installed Electricity Capacity by Source in Liberia in 2020 (MW)**

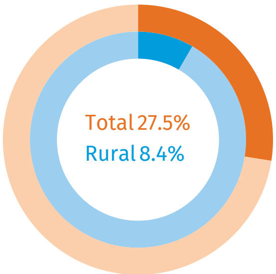


Source: IRENA[7]

In Liberia, the main electricity regulating body is the Liberia Electricity Regulatory Commission (LERC). LERC oversees the development and operation of the electricity sector as well issues licences for the generation, transmission, supply and import of electricity in the country. The main utility is the state-owned Liberia Electricity Corporation (LEC), founded in 1973. The LEC is in charge of the production, transmission and supply of electricity in the country.[8]

Liberia endured a 14-year civil war that greatly affected the country's infrastructure, including completely destroying the electricity sector. As a result, the electrification rate is one of the lowest in the world. In 2020, less than 28 per cent of the total population had access to electricity, with an 8 per cent access rate in rural areas (Figure 3).[9,10]

Figure 3. **Electrification Rate in Liberia in 2020 (%)**



Source: World Bank[9,10]

Considerable efforts have been undertaken by the Government of Liberia, international development partners and the LEC to rebuild and develop the electricity sector following the devastating damage from the civil war and post-war looting. Part of this effort was to construct addition transmission lines within the country. The Liberia Interconnected Transmission System operates at 66 kV and spans 128.7 kilometres and is expected to increase to over 248 kilometres upon completion of the ongoing transmission expansion projects. Some of these projects are the European Union–funded Monrovia Consolidation Project, the World Bank–funded Liberia Accelerated Electricity Expansion Project, the KfW Bank-funded Electrification and Grid Upgrade Project and the African Development Bank (AfDB)–funded Roberts International Airport corridor project.[8]

In line with the Sustainable Energy 4 All (SEforALL) initiative and the United Nations Sustainable Development Goals (SDGs), the Government of Liberia is committed to achieving a 20 per cent rural electrification rate as well as a total electrification of all county capitals, healthcare facilities and secondary schools by 2025. Under these initiatives, no country is to have an electrification rate below 15 per cent by 2030.[11]

Liberia is a member country of the Economic Community of West African States (ECOWAS). The ECOWAS Centre for Renewable Energy and Energy Efficiency (ECREEE) aims to support the development of renewable energy sources and energy action plans in the member states. Liberia is also part of the West African Power Pool (WAPP), a regional organization dedicated to fostering greater cooperation in the region's power sector and interconnection among countries to enhance energy security.[12]

The electricity tariffs in Liberia are some of the highest in the ECOWAS region, ranging from 0.15 USD/kWh to 0.24 USD/kWh.[8]

SMALL HYDROPOWER SECTOR OVERVIEW

The definition of small hydropower (SHP) in Liberia conforms to that of the Economic Community of West African States (ECOWAS), which is up to 30 MW. There are currently two operational SHP plants in Liberia: a 4.8 MW plant in Harbel, Margibi, operated by the rubber-producing company Firestone Plantation Company and a 60 KW plant in Yandohun, Lofa. The total installed capacity of SHP in Liberia is 4.86 MW (Table 1).[13,14]

Table 1. **List of Operational Small Hydropower Plants in Liberia**

Name	*Location*	*Capacity (MW)*	*Operator*
Harbel	Margibi County	4.80	Firestone Plantation Company
Yandohun	Lofa County	0.06	Yandohun Electricity Development Cooperative

Source: Renewables Liberia[13,14]

In order to determine the SHP potential of Liberia, studies were conducted in 2015 by the European consultant company AFRY (then-Pöyry Energy GmbH) for the ECREEE. An estimated theoretical SHP potential of 592 MW was identified and published in the GIS Hydropower Resource Mapping and Climate Change Scenarios for the ECOWAS Region, Country Report for Liberia.[15] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, estimated potential increased considerably based on data from a more recent and thorough study, whereas the installed capacity has remained unchanged (Figure 4). Table 2 shows a list of some planned SHP projects.

RENEWABLE ENERGY POLICY

Liberia does not have a consolidated renewable energy policy document. In 2007, the Government of Liberia drafted a Renewable Energy and Energy Efficiency Policy and Action Plan (REEEPAP) that emphasizes the importance of renewable energy and prioritizes the creation of the Rural and Renewable Energy Agency (RREA). The RREA was subsequently created in 2010 with the mission to promote the commercial development and supply of energy in rural areas in order to facilitate their economic development. The REEEPAP also recognizes the great potential for and importance of SHP development.[21,22]

In addition to the REEEPAP, in 2009 the Government of Liberia developed a National Energy Policy (NEP) with a long-term strategy to achieve carbon neutrality in energy production and transformation by the year 2050. This strategy is aligned with Liberia Rising Vision 2030, the country's development strategy for inclusive development.[21]

Liberia is a signatory to the United Nations Framework Convention on Climate Change (UNFCCC), the Kyoto Protocol and the Paris Agreement. In 2021, the Government of Liberia updated its Nationally Determined Contribution (NDC) and, as part of its mitigation targets, commits to developing off-grid SHP by developing several sites with 20 MW capacity by 2030. The NDC also highlights the importance of solar power and commits to installing 10 MW of solar photovoltaic (PV) plants by 2025 through partnerships with independent power producers (IPPs).[21]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

SHP plants are regulated by the same legislation as larger hydropower projects. The main legislation and regulation documents in Liberia concerning hydropower projects are:

- The Electricity Law (2015);
- Executive Order No. 23 on the creation of the RREA (2010).

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The development of SHP in Liberia is mainly hampered by:

- The lack of a comprehensive renewable energy policy with a clear strategy for SHP development;
- Deficient electricity network due to extensive infrastructure damage from war;
- Lack of local capacity for the installation and maintenance of SHP plants;
- Limited availability of hydrological data.

Enablers for SHP development in Liberia include:

- Specific mention of the importance of SHP development in the country's NDC and REEEPAP;
- Plans to promote private sector investment in SHP as outlined in the country's NDC;
- Thorough assessment of SHP potential as outlined in the GIS Hydropower Resource Mapping and Climate Change Scenarios for the ECOWAS Region, Country Report for Liberia.

Mali

Davy Rutajoga, International Center on Small Hydro Power (ICSHP)

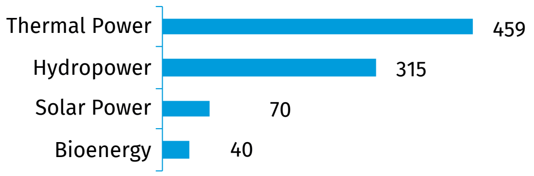
KEY FACTS

Population	20,250,834 (2020)[1]
Area	1,240,192 km^2[2]
Topography	Mali is a mostly flat country with occasional high-rising plateaux. Almost half of the country is covered by the Sahara Desert in the north. The open steppes of Akle Azaouad (AKA) plateau and the rocky terrain of Adrar-Timetrines and of Tilemsi from east to north. The southern part of the Sahara Desert in Mali transitions into the Sahel Region, interrupted in central Mali by the alluvial plains of the Inland Niger Delta. The majority of the country's agricultural land is found in southern Mali, in the plains of the Sudanian Region.[3]
Climate	Lying within the intertropical zone, Mali has a hot and dry climate as the sun nears its zenith throughout most of the year. There are two main seasons: dry and wet seasons. The dry season (November–June) is marked by high temperatures and low humidity, with daytime temperatures reaching 45 °C. The wet or rainy season (June-October) is characterized by gusty winds and heavy rainfall. Temperatures in the Sahara Desert can range from daytime extremes of 60 °C and night temperatures of 4 °C.[2]
Climate Change	Mali is affected by global warming, with mean annual temperatures having increased by 0.7 °C since 1960 at an average rate of 0.15 °C per decade. This increase is observed especially in the hot and dry season. The frequency of nights considered hot has increased considerably, except in the months of December to February. Droughts have also increased, particularly in the northern regions, and a decrease in rainfall has been observed.[4]
Rain Pattern	Mali experiences variable rainfall throughout the country, with the southern Sudanian regions receiving annual rainfall of between 510 mm and 1,400 mm and the Sahelian Region receiving between 200 mm and 510 mm. The mean annual precipitation in Mali is 322 mm.[2,4]
Hydrology	Two main rivers cut through Mali: the Senegal River and the Niger River. The Niger River, which runs through the country for over 1,600 km, flows north-east across the Mandingue Plateau and is interrupted by waterfalls and a dam at Sotuba. The Senegal River runs through Mali for 670 km and flows towards the Atlantic Ocean in a north-west direction.[2]

ELECTRICITY SECTOR OVERVIEW

The main sources of electricity in Mali are thermal power and hydropower, accounting for 61 per cent and 37 per cent, respectively, of total electricity production of 3,952 GWh in 2019. Bioenergy and solar energy contributed 67 GWh and 4 GWh, or less than 2 per cent and 0.1 per cent, respectively, of the total production that year (Figure 1).[5]

Figure 1. **Annual Electricity Generation by Source in Mali in 2019 (GWh)**

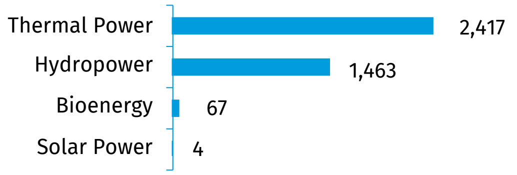


Source: IEA[5]

Most of the hydropower consumed in Mali is generated by the 200 MW Manantali hydropower plant, which also supplies most of the hydropower consumed by the neighbouring countries of Senegal and Mauritania, and by the 60 MW Felou plant shared with Senegal. Mali is also home to the largest solar plant in Western Africa: the 50 MW Kita plant. The electricity shared with neighbouring countries is part of the Synchronized Western Network, a subgroup of the West African Power Pool (WAPP) that connects four countries of the Economic Community of West African States (ECOWAS): Mali, Senegal, Niger and Burkina Faso.[5]

In 2020, Mali had 459 MW of installed thermal power capacity representing approximately 52 per cent of the total installed electricity capacity of 884 MW. Hydropower accounted for 315 MW or 36 per cent of the total installed capacity. Installed solar power and bioenergy capacities were 70 MW and 40 MW, respectively, or almost 8 per cent and 5 per cent of the total installed electricity capacity (Figure 2).[6]

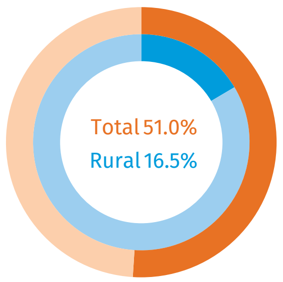
Figure 2. **Installed Electricity Capacity by Source in Mali in 2020 (MW).**



Source: IRENA[6]

In 2020, the total rate of access to electricity in Mali was 51 per cent, with the rural electrification rate being less than 17 per cent (Figure 3).[7]

Figure 3. **Electrification Rate in Mali in 2020 (%)**



Source: World Bank[7]

Electricity in Mali is supplied by Energie du Mali SA (EDM-SA) through three separate electric systems: the interconnected system, the isolated centres and the interconnection with the grid of Côte D'Ivoire. Until 2010, the EDM-SA was the sole entity allowed to produce, transmit, supply, commercialize and export electricity in Mali. Since 2010, the Electricity and Water Regulatory Board (CREE), which is mandated by a ministerial decree to regulate the electricity sector and clean water supply in urban centres, has been able to authorize third parties to access the national grid. Rural off-grid energy services with generation systems below 250 kW are provided by independent operators through the Malian Agency for the Development of Household Energy and Rural Electrification (AMADER).[8,9,10]

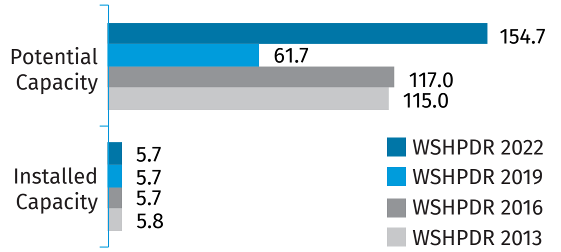
In 2001, the Government of Mali committed, through partnership, to the Sustainable Energy for All (SEforALL) with the aim of providing electricity access to at least 87 per cent of the population by 2030. In 2006, the Government debuted the National Energy Policy (PEN) to support and strengthen the energy sector and its contribution towards a sustainable economic and social development. In 2014, the Government launched the National Renewable Energy Action Plan 2013–2033 (PANER) in order to address the specific issue of renewable energy (RE).[8,11]

The electricity tariffs in Mali are subsidized by the Government and have not increased in any significant manner over the years. In 2018, the tariffs were between 0.11 USD/KWh and 0.25 USD/KWh. There are no recent tariffs published by official sources, however it can be assumed that they have not varied significantly.[12]

SMALL HYDROPOWER SECTOR OVERVIEW

In Mali, small hydropower (SHP) refers to plants with installed capacity of up to 30 MW. There is currently one operational SHP plant, the 5.7 MW run-of-river Sotuba plant. The country has an estimated SHP potential of up to 154.7 MW, a 150 per cent increase from the estimated potential in the *World Small Hydropower Development Report* (*WSHPDR*) *2019* (Figure 3). This increase is based on newer studies of various sites as included in the Renewables Readiness Assessment of Mali by the IRENA.[12]

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Mali (MW)**



Source: IRENA,[12] *WSHPDR 2013*,[13] *WSHPDR 2016*,[14] *WSHPDR 2019*[15]

In 2020, the Ministry of Energy and Water invited sealed bids for the design, commissioning, installation and supply of a 7.5 MW SHP plant in Djenné designed to supply 5,200 local households with electricity. The Djenné plant is one of the two SHP plants with a combined capacity of 8.9 MW that are being developed under the Mini-Hydropower Plants and Related Distribution Networks Development Project (PDM-Hydro), the other one being located in Talo. As of 2022, the Government was in the process of environmental and social audits in preparation for the construction of the SHP plants.[16,17]

Table 1. **List of Selected Planned Small Hydropower Projects in Mali**

Name	*Capacity (MW)*
Moussala	30.0
Taoussa	20.0
Gourbassi	13.0
Markala	10.0
Djenné	7.5
Sotuba II	6.0
Kourouba	3.9
Talo	1.4

Source: IRENA,[12] Hydropower & Dams,[16,17] GOPA-INTEC[18]

In addition to the Djenné and Talo plants, the Government launched a project to build a new 3.9 MW SHP plant on the Sankarani River. This plant, located in the Kourouba region, aims to bring electricity to approximately 20,000 people in the region. The consulting services for this project are courtesy of the German GOPA International Energy Consultants (GOPA-INTEC) and are financed by the African Development Bank (AfDB).[18]

RENEWABLE ENERGY POLICY

Concomitantly with the NEP, the Government of Mali formulated a National Strategy for the Development of Renewable Energies and, in 2008, a National Strategy for the Development of Biofuels. The objectives of these policies were to promote widespread use of RE technologies as well as creating the best conditions for the sustainability of RE services. The Latter policy emphasized the development of indigenous energy sources, which are renewable and readily available.[11] In 2011, the Climate Investment Fund (CIF) approved the Scaling up Renewable Energy Programme (SREP), which aimed to assist in the development of RE in Mali. The SREP comprised three investment projects:

- The Scatec project for the development of solar energy;
- The project to build solar photovoltaic (PV)/biofuel hybrid hydropower systems in rural areas;
- The Mini-Hydropower Plants and Related Distribution Networks Development Project (PDM-Hydro).[19]

The Scatec project has progressed with the company Scatec Solar and its partners signing an amendment with the Government of Mali, in 2019, for the production of solar energy. The project is funded by the Norwegian Agency for Development Corporation (NORAD), the International Finance Corporation (IFC) and AfDB. The funding also includes a concessional loan from the CIF of USD 20 million under the SREP. The Scatec project signed a power purchase agreement (PPA) with the EDM-SA in 2015 to build, own, operate and maintain a 33 MW solar power plant with a 51 per cent shareholding. Annual production of the plant is expected to be approximately 57 GWh.[19,20]

The PDM-Hydro project aims to enhance access to electricity in rural areas, particularly in the regional provinces of Mopti and Ségou where much of the studies were conducted. An estimated 12,500 households and economic operators are expected to be connected through the project.[19]

In 2014, the Government adopted the National Renewable Energy Action Plan 2013–2033 (PANER) and the National Energy Efficiency Plan (PANEE). The two strategies were merged in 2015 for a consolidated National Renewable Energy Action Plan (NREAP) that follows SEforALL guidelines and sets targets for 2030 including 1,416 MW of installed RE capacity.[11]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

The main legislation and regulation documents in Mali concerning hydropower projects are:

- Electricity Law No. 90-10/AN-RM (1990);
- Order No. 00-019/P-RM (2000) on the organization of the energy sector;
- Order No. 00-021/P-RM (2000) on the creation of the CREE.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Observed hydrological trends in the Niger Basin, where the Sotuba SHP plant is located, highlight a negative impact on the performance of the hydropower plant. Since 1907, a high inter-annual flow variability has been observed, culminating in a decrease in annual flow since 1970. In addition to this flow variability, a decrease in groundwater levels of tributaries to the Niger River has been observed, leading to a runoff deficit[11]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

SHP development in Mali is mainly hampered by:

- Difficult return on investment due to high investment costs and the need for an affordable price of kWh for poor households;
- Climate change affecting performance of hydropower plants through inter-annual flow variability;
- Concerns over the pollution of rivers due to the deployment of distribution lines, which may leave construction and packaging material onsite;
- Concerns of indigenous populations over changes to their lifestyles due to construction of power plants, such as pollution from construction through deposit of building and construction material;

Enablers for SHP development in Mali include:

- Government policies that focus on RE and the importance of mini-grid projects in rural areas encourage adequate solutions such as SHP;
- International funding for SHP projects through the PDM-Hydro project;
- The prospect of job creation brought about by construction, operation and maintenance of SHP plants, which would help alleviate social issues in Mali.

Mauritania

International Center on Small Hydro Power (ICSHP)

KEY FACTS

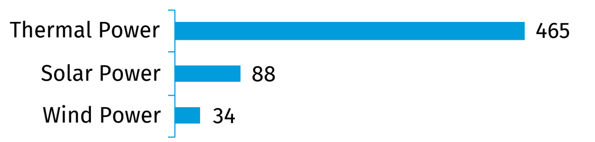
Population	4,649,660 (2020)[1]
Area	1,030,700 km^2 [2]
Topography	The country is generally flat with three geographic regions: a broad east-west band with vast plains and dunes; a narrow belt along the Senegal River to the south; and a large arid region to the north, which shades into the Sahara. Every year, the desert advances south several kilometres and brings shifting sand dunes. The highest point in the country is Mount Ijill, located near Fdérik and standing at 915 metres above sea level.[3]
Climate	Mauritania has a hot, dry and windy climate. There is sparse rainfall throughout the year for most of the territory, with the situation being worsened by the effects of rapid desertification. To the south, at the Sahelian border, the wet season is controlled by the Inter-Tropical Convergence Zone (ITCZ). The country's mean monthly temperature stays above 25 °C for most of the year, with peak temperatures of 33 °C in June and July.[4,5]
Climate Change	Mauritania is greatly affected by climate change, with the main consequences being the irregular rainfall patterns and the increasing temperatures in an already hot area. The mean annual temperature has increased by 0.9 °C since 1960 and is expected to further increase by 2-4.5 °C by 2080. The country has also been experiencing more frequent and more intensive bouts of droughts and floods, as well as a decrease in the water supply of the Senegal River. This poses a threat to the agricultural and fishing industries, which are essential for the country's economy. The global rise in sea level exposes the country to a risk of flooding of the infrastructure located on the coast. The sea level is projected to rise by 10 cm by 2030, 19 cm by 2050 and 36 cm by 2080. This risk is of particular concern to the capital and economic centre of Mauritania, Nouakchott, located on the shoreline.[5,6]
Rain Pattern	Most of Mauritania receives very little rainfall throughout the year. Annual precipitation ranges from 20 mm on the northern coast to approximately 400 mm in the central south. The southern region, at the edge of the Sahel, has a wet season between July and September with up to 200 mm of rainfall in each of those months. Changes in rainfall patterns are difficult to monitor as daily rainfall observations are limited.[5,7]
Hydrology	In Mauritania, surface water is the main water resource, of which the Senegal River and its tributaries constitute the main part. There are also considerable groundwater resources, though they are geographically disparate and play a very limited role in the country's social and economic context. Due to the country's location in a considerably arid region, there is a dependence on outside sources to meet the water demand.[8]

ELECTRICITY SECTOR OVERVIEW

The main source of electricity in Mauritania is thermal power, accounting for 863.4 GWh or almost 80 per cent of the 1,087.4 GWh generated in the country in 2020 (Figure 1). Wind and solar power accounted for approximately 11 per cent and 10 per cent of the total generation, respectively (or 115.3 GWh and 108.7 GWh).[9]

Electricity in Mauritania is owned, transmitted and distributed entirely by the Mauritanian Electricity Company (SOMELEC). There are no individual power producers in the country. SOMELEC, founded in 2001 following the demerger of the National Water and Electricity Company (SONELEC), operates in 58 cities and dozens of towns across Mauritania. The company also owns shares in the Manantali and Félou hydropower plants in neighbouring Mali.[9] In this report, the imported electricity from these plants is not accounted for in the total annual electricity generation of Mauritania, but rather in that of Mali.

Figure 1. **Annual Electricity Generation by Source in Mauritania in 2020 (GWh)**

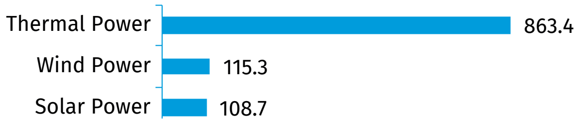


Source: SOMELEC[9]

The electricity sector of Mauritania is regulated by the Department of Electricity and Energy Management (DEME) of the Ministry of Petroleum, Energy and Mines (MPEM). DEME is in charge of both the national grid and off-grid electricity production. It regulates the work of SOMELEC and the Agency for the Development of Rural Electrification (ADER).[10]

In 2020, the total installed capacity in Mauritania was 587 MW, with the thermal power plants of SOMELEC accounting for 79 per cent (or 465 MW), the solar power farm accounting for 15 per cent (or 88 MW) and the wind farms accounting for 6 per cent (or 34 MW) (Figure 2).[11]

Figure 2. **Installed Electricity Capacity by Source in Mauritania in 2020 (MW)**

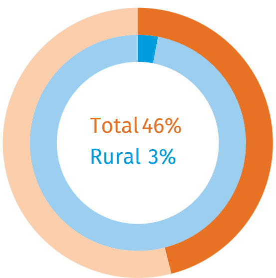


Source: IRENA[11]

As part of its Nationally Determined Contribution (NDC 2021–2030), Mauritania aims to reach a target of 13 GW of renewable energy in its energy mix by 2030.[6] The country also joined the Sustainable Energy for All (SE4ALL) initiative in 2014 and therefore adheres to the initiative's goal of doubling the share of renewable energy in the global energy mix by 2030.[12] The Government of Mauritania also aims to reach a national target rate of electrification of 70 per cent by 2030, with 95 per cent in urban areas and 40 per cent in rural areas as part of the country's Strategy for Accelerated Growth and Shared Prosperity (SCAPP) 2016–2030.[13]

As of 2020, the average price of electricity for a standardized connection in Mauritania was 0.176 USD/kWh.[14] In 2019, less than 46 per cent of the population had access to electricity, with 87 per cent in urban areas and 3 per cent in rural areas (Figure 3).[15,16,17]

Figure 3. **Electrification Rate in Mauritania in 2019 (%)**



Source: World Bank[15,16]

SMALL HYDROPOWER SECTOR OVERVIEW

There was no small hydropower (SHP) sector in Mauritania as of 2021. All existing plants in the country are large-scale and all hydropower generation is imported. The potential for SHP is unknown. However, the country is expected to have some limited SHP potential in the south, which could be exploited to provide electricity to smaller communities. This potential, however, still remains to be studied.[12]

RENEWABLE ENERGY POLICY

As part of the SCAPP, the Government of Mauritania aims to promote access to electricity in rural areas. There is, however, no official implementation plan for rural electrification policy. In 2014, the Renewable Readiness Assessment, launched by the International Renewable Energy Association (IRENA) and the United Nations Development Programme (UNDP) provided Mauritania with a study of the conditions and potential for renewable energy development. Following this assessment, the Government of Mauritania developed a high-priority renewable energy development programme for 2015–2018 as an alternative to the lacking integrated national electrification plan.[13] Since 2019, Mauritania has been part of the African Development Bank-led Desert to Power West Africa Regional Energy Programme (WAREP), which aims to provide access to electricity and enable socio-economic development in the Sahel region by harnessing the available solar power potential and adding 10 GW of solar photovoltaic generation capacity by 2025.[18]

The electricity sector of Mauritania is governed by the Electricity Code (2001–2019). The Master Plan for the Generation and Production of Electricity (2013), a long-term strategy for the development of the electricity sector in Mauritania, has been the main framework of reference for the future of the sector. However, it needs to be revised and updated to reflect the unsuccessful market liberalization strategy as SOMELEC retains monopoly of the electricity sector in the country.[13]

Due to the lack of a sufficient regulatory framework for access to sustainable energy, in 2017 Mauritania marked a relatively low score of 24 out of 100 on the World Bank Regulatory Indicators for Sustainable Energy (RISE) evaluation, placing it among the lowest scoring access-deficit countries in the world.[13]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

There is no legislation or regulations that target SHP in Mauritania. As the SHP potential is limited and there are no immediate plans for SHP development, the country's hydropower resources are all imported from Mali.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

As there are no SHP plants in Mauritania, the development of future plants is hindered by:

- The lack of sufficient data on hydropower resources

in the country;
- The lack of a comprehensive legal and regulatory framework;
- The focus of the Government's efforts on the development of other renewable energy sources with more potential, such as solar and wind power.

The known enabler for SHP development in Mauritania is:
- The SHP potential identified in the southern part of the country, which could provide some electricity to smaller communities.

Niger

International Center on Small Hydro Power (ICSHP)

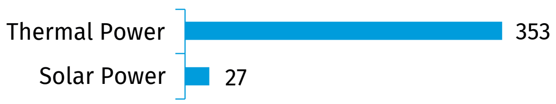
KEY FACTS

Population	24,206,636 (2020)[1]
Area	1,266,700 km^2 [2]
Topography	Niger is located in the Sahel region, a transitional zone between the Sahara Desert, which covers approximately 65 per cent of the country, and tropical Western Africa. This area is made up of shifting sand dunes, broad gravel and stony plains. Across central Niger, the pastoral areas of the Manga and Azouak regions form a wide streak of savannahs and steppes. Southern Niger is more productive, home to the Maradi-Zinder region, the largest agricultural region in the country.[3]
Climate	Niger is characterized by very high temperatures all year-round. An intense dry season from October to May is replaced by a brief, irregular rainy season brought about by the Western-African monsoon. The mean annual temperature is 27.9 °C with cooler temperatures in mountainous regions.[4]
Climate Change	Niger experiences the effects of global warming, with its mean annual temperature having increased by 0.6-0.8 °C between 1970 and 2010, higher than the global average. An increase in hotter days and nights has been observed. Rainfall has been variable from year to year and has not returned to the pre-1960s levels. The rainy seasons are shorter and harder, with an increase in extreme rainfall events and floods.[4]
Rain Pattern	With its irregular and brief rainy season, Niger enjoys relatively little rain, particularly in the northern regions, which experience 100–200 mm of rainfall. The southern regions enjoy more rain (500–600 mm), which is limited to the summer months of June–September. The mean annual precipitation is 179.6 mm.[4]
Hydrology	Niger is a dry country and has relatively poor hydrology. The main rivers in the country are: the Tapoa, Mékrou, Sirba, Dargol, Gorouol, Goroubi, Diamangou and the Niger River, the third largest river in Africa (4,200 kilometres in length, of which 500 kilometres run through Niger). Other important water bodies include Komadougou Yobé, Lake Chad and the ponds of Madarounfa, Tabalak and Guidimouni. There are important underground resources with a relatively deep groundwater level in the northern area of the country.[5]

ELECTRICITY SECTOR OVERVIEW

The main sources of electricity in Niger are thermal power and, to a much lesser extent, solar power. In 2019, the total electricity production amounted to approximately 555 GWh, of which thermal power accounted for 94 per cent, or 523 GWh, and solar power accounted for 6 per cent or 33 GWh (Figure 1).[6]

Figure 1. **Annual Electricity Generation by Source in Niger in 2019 (GWh)**

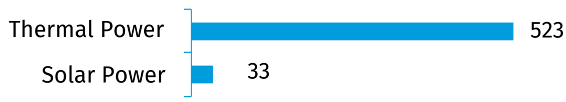


Source: IRENA[6]

The Niger Electricity Company (NIGELEC) was founded in 1968 and has a monopoly on transmission and distribution of electricity the country. In addition to the NIGELEC operations, the Coal Company of Anou Araren (SONICHAR) produces electricity from a thermal coal power plant and sells it to mining companies and has a quasi-monopoly on distribution in the cities of Agadez, Arlit and Tchirozérine.[7] The diesel and coal thermal power plants continue to play a major role in the production of electricity in the country, despite the fact that these facilities are relatively old and many have reached the age of decommissioning.[8]

In 2020, the total installed electricity capacity in Niger was 380 MW, of which thermal power represented 93 per cent. Installed solar power capacity amounted to 27 MW, or 7 per cent of total installed capacity (Figure 2).[6]

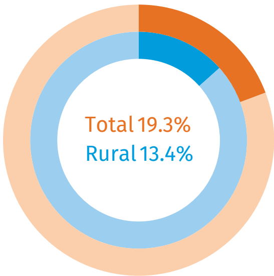
Figure 2. **Installed Electricity Capacity by Source in Niger in 2020 (MW)**



Source: IRENA[6]

The total electrification rate in Niger in 2020 was 19 per cent, with rural access being 13 per cent, one of the lowest in the region (Figure 3). By 2030, the country aims to reach 100 per cent electricity coverage in urban areas and 30 per cent in rural areas. According to the Project for the Electrification of Rural and Urban Areas (PEPERN), the plan should target at least 46,000 households.[9,10,11]

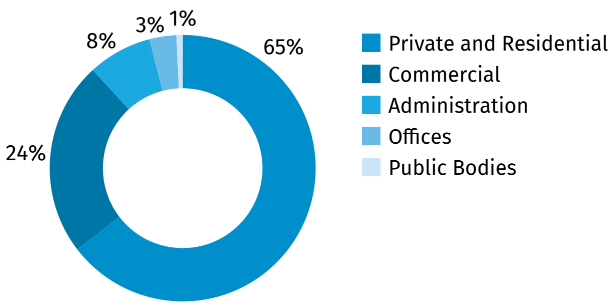
Figure 3. **Access to Electricity in Niger in 2020 (%)**



Source: World Bank[9]

In Niger, private and residential consumers represented the greatest share of electricity buyers (almost 65 per cent) and local public bodies the lowest (0.8 per cent) in 2020 (Table 1).[12]

Figure 4. **Consumption Rates by Consumer Category in Niger in 2020**



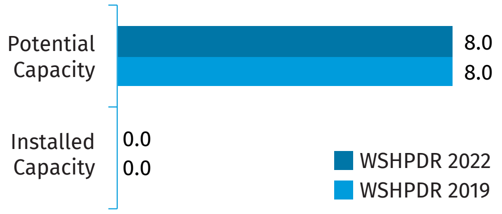
Source: NIGELEC[12]

The electricity subsector in Niger is regulated by the Regulation Authority of the Electricity Sector (ARSE), which is also responsible for advising the Ministry of Energy, Petroleum and Renewable Energies on electricity tariffs, among other duties.[13] Following Decree No. 2017-796/PRN/ME of 2017, electricity tariffs are fixed in Niger, between 0.097 USD/kWh and 0.22 USD/kWh depending on the consumer category (residential, commercial, etc.) and electricity requirement (low voltage, medium voltage, high voltage). There are also options for subscription-based billing for up to 21 USD per month.[14]

SMALL HYDROPOWER SECTOR OVERVIEW

Niger does not have an official definition for small hydropower (SHP). For the purposes of this chapter, the 10 MW definition will be followed. At the moment, Niger does not have any installed SHP capacity. A combined potential of 8 MW was identified on the four rivers that flow into the Niger River (Gorouol, Tapoa, Sirba and Mékrou). This potential remains untapped due to the seasonality of the Niger River's tributaries as well as the increase in droughts experienced by the country's water bodies. Both installed and potential capacity remain unchanged compared to the *World Small Hydropower Development Report (WSHPDR)* 2019 (Figure 5).[14,15]

Figure 5. **Small Hydropower Capacities in the WSHPDR 2019/2022 in Niger (MW)**



Source: Ministry of Energy, Petroleum and Renewable Energies,[14] *WSHPDR 2019*[15]

In 2019, construction began on the Niger River of a dam and a 130 MW hydropower plant. The project, called the Kandadji Dam Project, is expected to be completed in 2031 and is a first step towards the prospective development of hydropower in Niger.[16]

RENEWABLE ENERGY POLICY

Niger is a member of the Economic Community of West African States (ECOWAS) and as such adopted the National Renewable Energy Action Plan (NREAP) that all 15 member-states adopted in 2015. The NREAP addresses all sources of renewable energy, including wind power, solar power, thermal power, tidal power and hydropower, and highlights the importance of their development and the contribution that renewable energy would bring to the country.

The NREAP specifies the need for the development of hydropower through the construction of the 130 MW Kandadji plant, a 122 MW hydropower plant in Gambou and a 90 MW hydropower plant in Namarigoungou. These plants are expected to contribute greatly to the country's energy mix. Under the NREAP, Niger is committed to exploiting its renewable energy potential to achieve universal electricity coverage by 2030.[14]

The renewable energy potential in the country is mostly untapped. In 2018, with the support of the World Bank, Niger launched the Niger Solar Electricity Access Project (NESAP). The project of approximately USD 50 million (USD 4.4 million from a donation and a USD 45.55 million loan) aims at improving access to electricity through solar power. NESAP falls within the Renaissance Act 2 of the Republic of Niger aimed at improving the rural electrification rate. In order to reach its targets, Niger has received funds from the International Development Association (AID).[17]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

There is currently no legislation regulating SHP as there is no developed hydropower in Niger. The main legislation and regulations documents in Niger concerning the electricity subsector include:

- Law No. 2016-05 (2016) on the electricity code;
- Law No. 2015-58 (2015) on the creation of the ARSE;
- Order No. 2010-09 (2010) on the Water Code.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Extreme precipitation variability in the Sahel region has affected hydropower in the Sahelian countries. This variability has also resulted in increased droughts and seasonality of the Niger River's tributaries, which considerably affects SHP development prospects.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The development of SHP projects in Niger is mainly hampered by:

- Irregularity of rainfall patterns, which affects SHP development, further exacerbated by climate change;
- Lack of comprehensive renewable energy policy which would set specific goals, including for hydropower;
- Limited experience in hydropower as there is currently no hydropower plant in the country, although construction has begun on one and is expected to be completed in 2031;
- Dependence on fossil fuels for energy production.

Enablers for SHP development in Niger include:

- Its location within the ECOWAS region, which provides an opportunity for the country to learn from and acquire expertise in hydropower from other member countries with developed SHP;
- Identified SHP potential, which, if developed, would improve electrification rates in the country.

Nigeria

Paola Estenssoro Solíz and Cleber Romao Grisi, WHITEnergy Bolivia

KEY FACTS

Population	206,139,587 (est. 2020)[1]
Area	923,768 km^2 [2]
Topography	Nigeria is dominated by plains in the north and the south, with an average elevation of 609.5 metres. In the north, the Jos Plateau rises abruptly to a height of 1,219 metres in the Hausa Plains, reaching 1,781.6 metres in the Shere Hills. The eastern border with Cameroon is marked by an almost continuous chain of mountains, the Eastern Highlands, which rise to approximately 2,419 metres at the Chappal Waddi, the highest point in Nigeria. The Atlantic coastline is in the south of the country.[3]
Climate	Nigeria has a tropical climate with rainy and dry seasons, which vary depending on the location. The climate is hot and wet most of the year in the south-east of the country, but dry in the south-west and further inland. In the south, the rainy season lasts from March to November with a short dry season during August, referred to as the August Break, whereas in the far north it lasts from mid-May to September. The temperatures also vary a lot: in the north, winters are warm and dry reaching up to 40 °C, while northern hilly areas occasionally experience temperatures close to freezing (0 °C). By February, temperatures increase across all inland areas, reaching 40 °C in the centre-north from March to May. From June to September, the air is humid and sky is usually cloudy throughout the country, with uniform temperatures of 28–30 °C.[4,5]
Climate Change	Climate change projections for Nigeria predict an increase in maximum temperatures of 1.8–2.2 °C by the middle of the 21st century and of 2.2–4.5 °C by the end of the century, relative to the 1970–2000 period. The increase in maximum temperatures is expected to be the highest in the northern inland parts of the country, moderate in the centre and lowest in the coastal areas. This would reverse the trend observed during the 1970–2000 period, when the increase in temperatures was more significant on the coast than inland.[6]
Rain Pattern	The mean annual rainfall in the country is between 2,540 mm and 4,064 mm. The driest area in the country is the extreme north-east, where the average annual precipitation is below 500 mm, while in the central region it exceeds 2,000 mm and in the south-east 3,000 mm. The north of the country is drier than the south due to the influence of the coast line.[3,5,7]
Hydrology	There are three major basins in Nigeria: the Niger-Benue basin, the Lake Chad basin and the Gulf of Guinea basin. The Niger and the Benue Rivers are the two most important rivers in Nigeria. The two rivers converge at Lokoja forming a Y-shaped confluence and flow into the Niger Delta, one of the world's largest arcuate fan-shaped river deltas, before discharging into the Atlantic Ocean. Rivers in Nigeria generally show a marked seasonal variation in stages and discharges. The distribution of average monthly water levels at some gauging stations shows that a large proportion of the annual runoff occurs in the rainy season, occasionally causing floods. During the dry season, some of the smaller streams, especially in the northern parts of the country, virtually dry up, while the larger rivers are reduced to only a small fraction of their rainy season discharge.[3,4]

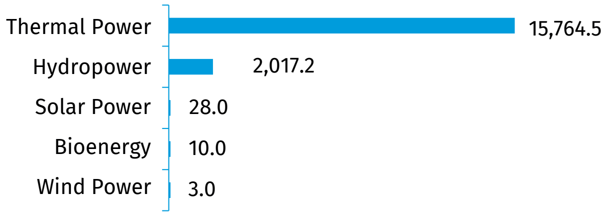
ELECTRICITY SECTOR OVERVIEW

As of 2020, Nigeria had a total installed capacity of 17,822.7 MW. Of this total, thermal power accounted for 15,764.5 MW (88 per cent), primarily provided by gas-fired power plants. Hydropower provided 2,017.2 MW (11 per cent) and the remaining 41 MW (less than 1 per cent) were provided by wind power, solar power and bioenergy (Figure 1).[8,9,10,11]

Most of the electricity capacity in Nigeria is connected to the national grid, with the exception of small hydropower (SHP) and wind power. Since the electricity supply from the national grid is insufficient and unstable, electricity production on isolated networks, mainly for self-consumption, plays a prominent role in the country.[12]

In 2021, there were 29 power plants suppling electric energy to the national grid, of which 4 were hydropower plants and 25 thermal plants. The main sources of hydropower are the Kainji (760 MW), Jebba (570 MW) and Shiroro (600 MW) hydropower plants.[8,9,13]

Figure 1. **Installed Electricity Capacity by Source in Nigeria in 2020 (MW)**

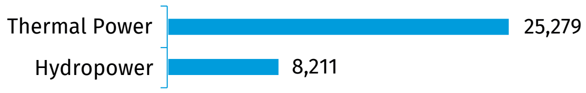


Source: NERC,[8,9] IRENA,[10] Romao Grisi & Estenssoro Solíz[11]

The transmission network of the national gird has a total length of 12,300 kilometres (5,650 kilometres of 330 kV lines and 6.687 kilometres of 132 kV lines) and connects 32 330 kV and 105 132 kV substations. The distribution network has a length of 224,838 kilometres consisting of 33 kV, 11 kV and low-voltage lines.[14]

In 2019, the generation of electricity in Nigeria was approximately 33,489 GWh. Thermal power provided nearly 25,279 GWh (75 per cent) of this total and hydropower provided nearly 8,211 GWh (25 per cent), while generation from other energy sources was negligible (Figure 2).[9]

Figure 2. **Annual Electricity Generation by Source in Nigeria in 2019 (GWh)**

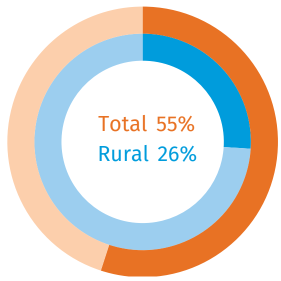


Source: NERC[9]

Although Nigeria is the largest economy in Africa, the national electrification rate stood at 60 per cent in 2018, leaving approximately 16 million households without access to electricity.[15] In 2019, nationwide electricity access declined to slightly over 55 per cent, urban electricity access stood at 84 per cent, while rural electricity access was approximately 26 per cent (Figure 3).[16] The majority of the rural population in Nigeria do not have access to electricity and shortages of electric energy production in rural areas hinder the development of the country.[12,17] In addition, the electricity supply in most parts of the country is unreliable due to frequent power outages caused by failures occurring on the main transmission grid as well as on the distribution networks, forcing consumers (both industrial and residential) to rely on diesel or petrol generators to meet their electricity needs.

The national electricity regulator is the Nigerian Electricity Regulatory Commission (NERC), an independent regulatory body established in 2005 as part of a process that effectively ushered in the privatization of electric power services in the country. The primary function of the NERC is to regulate electricity tariffs issued by both private and public generating companies. Additional responsibilities of the NERC include licensing operators, determining codes and standards, establishing customer rights and obligations and setting cost-reflective industry tariffs. Since its inception, the NERC has worked to facilitate the expansion of generating capacity and the national grid through the issuance of licences for the generation, transmission and distribution of electricity, as well as the development of codes and industry standards, market rules and a multi-year tariff structure.[18]

Figure 3. **Electricity Access Rate in Nigeria in 2019 (%)**



Source: World Bank[16]

In March 2020, the NERC initialized a transition from demand-based to cost-reflective and service-reflective electricity tariffs. Following these changes, consumer tariff rates are now based on the duration of the daily electricity service, with different service duration minimums applied to each of the five consumer classes:

- Residential (R): A consumer who uses the premises exclusively as a residence — house, flat or multi-storied house; minimum daily duration of service of 20 hours;
- Commercial (C): A consumer who uses the premises for any purpose other than exclusively as a residence or as a factory for manufacturing goods; minimum of 16 hours;
- Industrial (D): A consumer who uses the premises for manufacturing goods, including welding and ironmongery; minimum of 12 hours;
- Special (A): Consumers such as agriculture and agro-allied industries, water boards, religious houses, government and teaching hospitals, government research institutes and educational establishments; minimum of 8 hours;
- Street Lights (S): minimum of 4 hours.[18,19]

Additionally, electricity tariffs in Nigeria vary by region as well as by connection type for each consumer class. Table 1 displays residential tariffs across different regions of Nigeria in 2022. It must be noted than although the tariffs have been on a decreasing trend in recent years, they are still relatively high, as the duration of supply is limited and only a fraction of the population is connected to the grid in many areas.

Table 1. **Electricity Distribution Tariffs for Residential Users in Nigeria in 2022**

Region	*Price by connection type (NGN/kWh (USD/kWh))*				
	Lifeline	*Single-phase*	*Three-phase*	*Low-voltage maximum demand*	*High-voltage maximum demand*
Abuja	4.00 (0.010)	19.51 (0.047)		37.12 (0.089)	
Benin	4.00 (0.010)	24.49 (0.059)	26.94 (0.065)	31.69 (0.076)

SMALL HYDROPOWER SECTOR OVERVIEW

Hydropower in Nigeria is classified into six categories based on the range of installed capacity (Table 2). According to the national definition, small hydropower (SHP) includes plants between 1 MW and 30 MW of installed capacity.[21] In the current chapter, the national SHP definition of up to 30 MW is used for the purpose of comparing data with the *World Small Hydropower Development Report (WSHPDR) 2019*.

Table 2. **Classification of Hydropower in Nigeria**

Category	*Installed capacity (MW)*
Pico	P < 0.1
Micro	0.1 ≤ P < 0.5
Mini	0.5 ≤ P < 1
Small	1 ≤ P < 30
Medium	30 ≤ P < 100
Large	P > 100

Source: Fagbohun,[12] Imo et al.[21]

SHP projects are generally considered in Nigeria to be more environmentally friendly than both large hydropower plants and power plants running on fossil fuels, because SHP projects generally do not involve significant deforestation or inundation of the surrounding area. The net cost savings resulting from the use of local materials and labour, standardized power plants and the relative ease of local development of the SHP technology make it attractive for remote and off-grid applications, while directly benefiting rural communities.[22,23] The diverse topography and abundant watercourses of Nigeria are likewise suitable for SHP.

There were 14 SHP plants up to 30 MW operating in Nigeria as of 2021, with a total installed capacity of 57.2 MW (Table 3).[12,21,22,24,25,26] All existing SHP plants are not connected to the national grid and mostly provide power to remote rural areas. The theoretical potential capacity for SHP up to 30 MW has been estimated at 3,500 MW, indicating that less than 2 per cent of the potential has been developed so far, while the economically-feasible undeveloped potential has been estimated at 734.3 MW.[12,27,28] Relative to the *World Small Hydropower Development Report (WSHPDR) 2019*, installed capacity decreased by nearly 11 per cent while potential capacity decreased slightly by less than 1 per cent, due to more accurate information becoming available (Figure 4).[29]

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Nigeria (MW)**

	Total	**57.183**

Source: Fagbohun,[12] Imo et al,[21] Muhammadu & Usman,[22] Zarma,[24] Igweonu & Joshua,[25] Onyemaechi & Charles[26]

Over the last decade, several new SHP projects have been launched in the country (Table 4). However, their current status and stage of completion are unclear. Additionally, studies have identified 278 potential SHP sites up to 30 MW with a total potential capacity of 734.3 MW.[12] Several potential undeveloped SHP sites available for investment are listed in Table 5. According to some estimates, a total demand of 3,315 MW could be fulfilled by SHP in Nigeria by 2030, provided sufficient investment is made.[22]

Table 4. **List of Selected Ongoing Small Hydropower Projects in Nigeria**

Name	Location	Capacity (MW)	Development stage
Challawa Gorge Dam	Kano	7.00	Dam construction completed; electromechanical system yet to be installed
Ikere Gorge Iseyin	Oyo	6.00	Dam construction completed; electromechanical system yet to be installed
Annoke Ugbokpo	Benue	1.20	Dam construction completed; electromechanical system yet to be installed

RENEWABLE ENERGY POLICY

Nigeria is actively in the process of developing renewable energy policies and strategic documents. In 2006, the Energy Commission of Nigeria (ECN) and the United Nations Development Programme (UNDP) created the Renewable Energy Master Plan (REMP), with a subsequent review in 2012.[32] The former Ministry of Power and Steel, in collaboration with the International Centre for Energy, Environment and Development (ICEED) put together the Renewable Electricity Policy Guidelines in 2006, focusing on the use of small-scale renewable energy sources for rural electrification, and launched the Renewable Electricity Action Programme (REAP) operationalizing the guidelines the same year. The Japan International Cooperation Agency (JICA), in collaboration with the Federal Ministry of Water Resources (FMWR), put together several Hydropower Master Plans in 1993, 1995 and 2013 and in 2007 the Solar Energy Master Plan. In 2007, the Nigerian National Petroleum Corporation (NNPC) issued the National Biofuel Policy and Incentives, which established a biofuel support programme aiming at integrating the agricultural sector with the downstream petroleum sector. Finally, the National Renewable Energy and Energy Efficiency Policy (NREEEP), adopted in 2015, provides an overarching framework for the development of renewable energy sources and energy efficiency, thereby functioning as an umbrella policy for the various existing documents.[12,23,25]

With regard to hydropower development, the aforementioned legislation, programmes and frameworks aim to fulfil the following goals:

- Fully harnessing the hydropower potential available in the country for electricity generation;
- Giving particular attention to the development of mini- and micro-hydropower projects;
- The exploitation of hydropower resources shall be done in an environmentally sustainable manner;
- The active promotion of private sector and indigenous participation in hydropower development.[25]

An important overarching development that had positive impacts on the expansion of renewable energy sources in Nigeria was the 2005 Electricity Sector Reform Law. The Law allowed private operators to apply for and obtain a licence through the NERC to build and operate a power plant with an aggregate capacity greater than 1 MW. The Law additionally established the Rural Electrification Agency (REA) together with an independent Rural Electrification Fund (REF), which holds as its primary objective the full integration of renewable energy sources into the energy options available for rural electrification.[23]

In February 2018, Nigeria completed the Renewable Energy and Energy Efficiency Partnership project, which supplied 261,938 citizens with clean renewable energy. This project was implemented in partnership with the US Agency for International Development (USAID), private donors, government agencies, financial institutions and non-governmental organizations. The goal of the project was to build connections to 2.5 MW of power through off- and on-grid sources, which is expected to reduce CO_2 emissions by 4.5 million metric tons.[33]

SMALL HYDROPOWER LEGISLATION AND REGULATION

The Federal Ministry of Environment (FME) is responsible for environmental impact assessment (EIA), to be implemented in accordance with the Environmental Impact Assessment Act (Decree No. 86) of 1992 and the guidelines promulgated in 1995. All development projects are classified in one of the following three categories based on the guidelines:

- Projects requiring a full EIA;
- Projects requiring a partial EIA primarily focused on environmental impact mitigation measures and an environmental plan (although a full-scale EIA is required if a project site is adjacent to an area with special environmental and social considerations);
- Projects with "essentially favourable impacts" on the environment, for which the FME prepares a simple environmental impact statement.

Additionally, the Policy for Managing Effluents and Discharges replaces the EIA with a simplified procedure for off-grid hydropower and captive generation below 10 MW.[14]

COST OF SMALL HYDROPOWER DEVELOPMENT

The purchase price of electricity from SHP plants in Nigeria necessary to ensure project payback within a reasonable timeframe ranges between 0.03 USD/kWh and 0.06 USD/kWh, making SHP an attractive source of electricity generation. The comparative costs of different renewable energy sources in Nigeria are provided in Table 6.[25]

Table 6. **Comparative Cost of RES development in Nigeria**

Technology	*Initial capital cost (USD/kW)*
Micro-hydropower, 10-20 kW	1,000–2,400
Solar power (PV), 0.070 kW	11,200
Solar power (PV), 0.090 kW	8,400
Wind power, 0.025 kW	5,500
Wind power, 4 kW	3,900
Wind power, 10 kW	2,800

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The main barriers faced by the SHP sector in Nigeria include:

- Inadequate policy, institutional and regulatory frameworks to stimulate demand and attract investors. Although several policies and regulatory frameworks are in place to promote renewable energy-based electricity generation, there is no definite and well-framed pathway to making these policies successful.
- High initial investment costs of SHP development relative to those for large hydropower.
- Inadequate private sector participation in SHP development. So far, the private sector is only actively involved in the importation and marketing of renewable energy components. Full participation by the private sector in all aspects of SHP development, especially in the form of investment towards local fabrication of turbines, will enhance the development of SHP.
- Limited access to relevant data. The recent unbundling of the Power Holding Company of Nigeria into different companies under the privatization programme has made the process of acquiring relevant data for SHP development challenging.
- Lack of public awareness of the potential and benefits of SHP as a viable source for electricity generation.
- Insufficient skilled labour for developing SHP projects.

The primary enablers for SHP development in the country could be defined as:

- The very significant untapped potential SHP capacity;
- The urgent need to extend electrification to many parts of the country undersupplied with electricity and beyond the reach of the current transmission and distribution networks.

Senegal

Davy Rutajoga, International Center on Small Hydro Power (ICSHP)

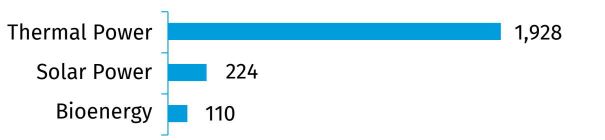
KEY FACTS

Population	16,743,930 (2020)[1]
Area	196,722 km^2 [2]
Topography	Senegal is a relatively flat country within the depression known as the Senegal-Mauritanian Basin. The north of the country presents dunes from Cap Vert to Saint-Louis. The south has muddy estuaries and includes the greener Casamance Region, which presents a more varied relief and is separated from the rest of the country by the Republic of the Gambia. The south-east is home to the Tamgué foothills, which rise up to a maximum altitude of 581 metres. The north-west is mostly a semi-desert, but the centre and much of the south, except for the forests of the Casamance, are open savannah country.[3]
Climate	Senegal has a tropical dry climate with three climate zones (coastal, Sahelian and Sudanic) and two distinct seasons: a dry season from October to May and a rainy season from June to September. The mean annual temperature is 28.6 °C, while the monthly averages in the hottest seasons can reach 35 °C. The colder months can bring temperatures as low as 14 °C, particularly in January.[4,5]
Climate Change	Between 1961 and 2010, Senegal has seen an overall increase in temperatures ranging from 0.58 °C to 1.88 °C. Decreases in precipitation were also recorded as well as irregular and unpredictable rainfall patterns throughout the country. There has been an increase in both droughts and floods in recent years and a recorded rise in sea level.[4]
Rain Pattern	The coastal climate zone, which occurs along the Atlantic coastline, experiences rainfall from June to October with an average annual rainfall of approximately 500 mm. The Sahelian climate zone, an area between the Senegal River to the north and a line running from the town of Thiès to the neighbouring Mali, experiences average precipitations of 360 mm. The Sudanic climate zone occurs in the southern half of the country and brings precipitation averages between 740 mm and 1,270 mm. The mean annual precipitation in Senegal is 713.8 mm.[4,5]
Hydrology	The main rivers in Senegal are the Senegal, Gambia and Casamance Rivers. The Senegal River, considered the most important waterway as it passes a long route through the interior of the country, flows through the mountain masses of the east, rising at the Fouta Djallon foothills and rapidly falls before reaching the Senegalese territory. The river then forms the False Delta at Dagana, supplying Lake Guier.[2]

ELECTRICITY SECTOR OVERVIEW

The main sources of electricity in Senegal are thermal power and solar power, accounting for 85 per cent and 10 per cent, respectively, of the total electricity production of 2,263 GWh in 2019. Production from renewable bioenergy accounted for 110 GWh, or 5 per cent of the total production, in 2019 (Figure 1).[6]

Figure 1. **Annual Electricity Generation by Source in Senegal in 2019 (GWh)**



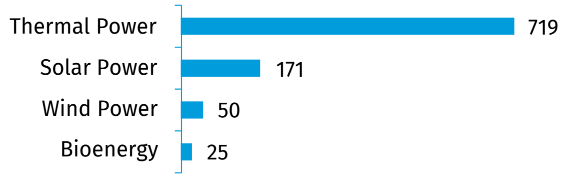
Source: IRENA[6]

The electricity sector in Senegal is overseen by the Ministry of Petroleum and Energy and regulated by the Regulatory Commission for Electricity Sector (CRSE). The CRSE works with Senelec, the national utility, and the Agency for Rural Electrification (ASER) to regulate production, supply and distribution within the country and in the regional West African Power Pool (WAPP).[7]

In Senegal, independent power producers (IPP) have a relatively strong presence and contribute greatly to electricity generation. This is a result of Law No. 98-29 of 1998 that created the ASER, which oversees public-private partnerships for the development of the electricity sector and attracts IPPs. These IPPs include the Moroccan ONE, EDF-Matforce, ENCO/ISOFOTON Maroc, the group STEG-Coselec-LCS, Kolda Energy and Electricité du RIP (EDR), all operating in rural Senegal.[8,9]

In 2020, power plants in Senegal had a combined installed capacity totalling 965 MW, of which thermal power, solar power, wind power and renewable bioenergy contributed 719 MW (or 74 per cent), 171 MW (or 18 per cent), 50 MW (or 5 per cent) and 25 MW (or 3 per cent), respectively (Figure 2).

Figure 2. **Installed Electricity Capacity by Source in Senegal in 2020 (MW)**

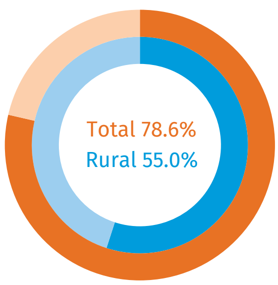


Source: IRENA[6]

Senegal is a member country of the Economic Community of West African States (ECOWAS). The ECOWAS Centre for Renewable Energy and Energy Efficiency (ECREEE) aims to support the development of renewable energy sources and energy action plans in the member states. Senegal is also part of the West African Power Pool (WAPP), a regional organization dedicated to fostering greater cooperation in the region's power sector and interconnection among countries to enhance energy security.[10]

Senegal has one of the highest electrification rates in Africa at almost 79 per cent in 2020, with a 55 per cent rural access rate (Figure 3).[11]

Figure 3. **Electrification Rate in Senegal in 2020 (%)**



Source: World Bank[11]

Electricity tariffs in Senegal vary depending on the provider, though not considerably. The largest provider is, by far, Senelec, which in 2020 charged tariffs ranging from 0.15 USD/kWh to 0.29 USD/kWh depending on the level of consumption. The tariffs are set by the CRSE.[9]

SMALL HYDROPOWER SECTOR OVERVIEW

Small hydropower (SHP) in Senegal refers to hydropower plants with a capacity of up to 10 MW. There are currently no SHP plants on the territory of Senegal and no potential sites have been officially identified due the flat topography of the country that is unfavourable for the development of SHP.

RENEWABLE ENERGY POLICY

Senegal was one of the first countries in West Africa to pass a renewable energy (RE) law, the Renewable Energy Policy Law of 2010, and is one of the most committed to strengthening institutional framework in the RE sector.[12]

The Government of Senegal launched the Energy Sector Development Policy Letter of 31 October 2012, pursuant to Act No. 2010-21 on the Renewable Energy Policy Law of 20 December 2010 and Decree No. 2011-2013 on the Implementation of the Renewable Energy Act. The decree set the conditions for the purchase and remuneration of electricity from RE sources. The Renewable Energy Law provides a legal framework for tax exemptions for the purchase of equipment necessary to develop RE production for domestic use. The law also created the foundation for a feed-in tariff (FIT) scheme.[8,13]

In order to promote and develop the RE sector through a favourable legislative and regulatory framework, the National Renewable Energy Agency (ANER) was created by Order 2013-684 and a Centre for Studies and Research into Renewable Energy was launched at the University Cheikh Anta Diop of Dakar for the purpose of conducting studies on RE potential in Senegal.[13]

The national economic and social development plan of Senegal, the Plan for an Emerging Senegal (PSE 2025), highlights the importance of RE development in the country through the goal of at least a 23 per cent share of on-grid RE in power generation by 2030. As part of the PSE 2025, a National Action Plan for Renewable Energies (PANER) was designed with specific targets for 2025, including:

- Power of 440 MW from different sources (solar photovoltaics (PV) and wind power);
- RE penetration rate of 30 per cent.[13]

In the capital city of Dakar, the Environmental Action Plan (PACTE) and the Master Plan for Urban Development of Dakar and Its Surroundings (PDU 2035) aim for a 15 per cent share of RE and a reduction of diesel share in local generation mix from 90 per cent in 2013 to 5 per cent by 2035. The City of Dakar has also finalized the Territorial Energy Climate Plan (PCET), an integrated energy and climate change development plan informing the city's short- and long-term RE roadmap as part of its commitment to the C40 Cities Leadership Programme. Through the PCET, the Government of Senegal also plans to equip over half of all municipal buildings in the capital with rooftop grid-connected solar PV by 2030.[14]

BARRIERS AND ENABLERS TO SMALL HYDROPOWER DEVELOPMENT

The development of SHP projects in Senegal is hampered mainly by:

- Flat terrain;
- Deficient infrastructure, as there is inadequate maintenance of larger hydropower plants;

- Lack of local capacity for the installation and maintenance of SHP plants;
- Limited comprehensive mapping of RE sources in key areas;
- Limited availability of hydrological data.

Enablers for SHP development in Senegal include:
- Government support for the development of RE in general;
- Strong institutional framework for RE, including large hydropower, which could be reformed to include SHP.

Sierra Leone

International Center on Small Hydro Power (ICSHP)

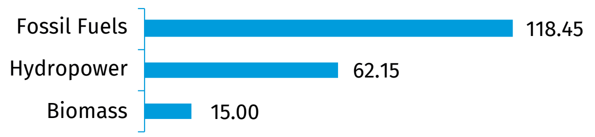
KEY FACTS

Population	8,238,175 (2022)[1]
Area	71,740 km²[2]
Topography	The western part of the country, the Sierra Leone Peninsula, is a mountainous area that slopes down to the coastal plain in the east and extends inland for 100–160 kilometres. The north-east is characterized by stretches of wooded hills that lead to a plateau region lying at an elevation of 300–610 metres. The highest point is Loma Mansa (Bintimani) at 1,948 metres. The relief is drained by a system of rivers flowing through cataracts and waterfalls. They are navigable for short distances and are ideal for hydropower development and providing water for the rural communities.[3,4]
Climate	Sierra Leone has a tropical climate, with inland areas having a temperate climate and coastal areas having a hot and humid weather. The annual temperatures average 26.5 °C. The dry season lasts from November to April, brings harmattan winds from the Sahara Desert and results in sandstorms and little precipitation. The wet season, lasting from May to October, is characterized by winds from the south-western monsoon.[3,5]
Climate Change	Sierra Leone has been experiencing increasing dry spells, which, combined with low-moisture content in the soil, affect farming production. Dry spells are often interrupted by torrential rains making the rainfall pattern irregular and harder to adapt to. The rise in sea level has also translated into frequent and severe floods, which, combined with deforestation, saturate the soil leading to catastrophic mudslides and landslides. The annual precipitation pattern has become erratic in the last 50 years, with delayed starts to the rainy season. The pre-monsoon period from April to June has come to be associated with more frequent rains and storms as well as stronger winds. The September to November period, which was characterized by rather frequent thunderstorms usually, has become calmer and drier. The harmattan has also been observed to be warmer in recent years and the average annual temperatures have increased by 0.8 °C since 1960.[4,5,6]
Rain Pattern	The coast and the mountains receive more than 5,800 mm of rainfall annually, while the rest of the country receives approximately 3,150 mm. There are three climatic belts: from the coast to 80 kilometres inland, with rainfall greater than 3,300 mm per annum; 80–190 kilometres inland, with an average annual rainfall of 2,500–3,300 mm; and from 190 kilometres inland to the border areas, with an average annual rainfall of 1,900–2,500 mm.[3,4,5]
Hydrology	The country has 12 river basins. Five are shared with Guinea and two with Liberia. The most important rivers are the Kolente (Great Scarcies), Kaba, Rokel, Pampana (Jong), Sewa, Moa and Mano. Seasonal variation affects the flow, which is lowest in April, as only 11–17 per cent of discharge occurs from December to April.[3]

ELECTRICITY SECTOR OVERVIEW

The energy sector in Sierra Leone is heavily dependent on imported petroleum, hydropower and biomass. Of the 195.6 MW of installed capacity in 2020, renewable energy accounted for 39 per cent and petroleum accounted for 61 per cent (Figure 1). The total electricity generated in the same year was 696 GWh, of which renewable energy represented 45 per cent and fossil fuel 55 per cent.[7]

Figure 1. **Installed Electricity Capacity by Source in Sierra Leone in 2020 (MW)**



Source: AF-Mercados (IRP)[7]

There are recent projects to increase electricity supply to Sierra Leone. These include the completed Cote D'Ivoire-Liberia-Sierra Leone-Guinea (CLSLG) transmission line, which, for Sierra Leone, consists of a 225 kV power line that covers the districts of Kenema, Pujehun, Kono, Koinadugu, Tonkolili, Kambia, Bombali and Karene. There is also an Exim Bank–funded project for the construction of a 225 kV power line passing through the towns of Yiben, Fadugu, Port Loko, Waterloo, Kent, Sussex and Goderich. The United Kingdom Foreign, Commonwealth and Development Office (FCDO) and the United States Trade and Development Agency (USTDA) are funding the Rural Renewable Energy Project, aiming to bring mini-grid renewable energy connection to approximately 154 locations in Sierra Leone.[8,9,10]

Sierra Leone remains one of the countries with the lowest rates of electrification, with 84 per cent of the country lacking access to electricity in 2018.[11] The country's urban and rural electrification rates were 53 per cent and 6 per cent, respectively, in the same year (Figure 2). The rates of electrification for the main cities as of 2021 are shown in Table 1.

The electricity in Sierra Leone is generated under the responsibility of the Electricity Generation and Transmission Company (EGTC), which was founded under the National Electricity Act of 2011. The electricity is distributed and supplied by the Government-owned Electricity Distribution and Supply Authority (EDSA), founded in 2014 after the unbundling of the National Power Authority (NPA).[13]

To remedy the instability of the electricity sector in the country, in 2018 the Government, through EDSA, entered into a five-year agreement with the Turkish power ship company Karpowership to supply the capital city of Freetown with electricity. The first power ship, Karadeniz Powership Doğan Bey, was commissioned to supply 50 MW for seven months and 30 MW for five months to Freetown for a period of three years. A second power ship, Karadeniz Powership Göktay Bey, was commissioned and began operations in Cline Town Bay in 2019. Since June 2020, a new agreement signed by EDSA aims to extend the contract with Karpowerhip for five more years for a capacity of 63 MW during the dry season and 23 MW during the wet season. As of 2021, Karpowership supplied Sierra Leone with 80 per cent of its electricity needs.[14]

Electricity tariffs in Sierra Leone are established by EDSA (Table 2).

Table 2. **Average Electricity Tariffs in Sierra Leone**

Consumer type	*Units (kWh)*	*Average electricity tariff (USD/kWh)*	*GST* (USD)*	*Tariffs incl. GST (USD)*	*Service charge (USD)*

Sierra Leone is a member country of the Economic Community of West African States (ECOWAS). The ECOWAS Centre for Renewable Energy and Energy Efficiency (ECREEE) aims to support the development of renewable energy sources and energy action plans in the member states. Sierra Leone is also part of the West African Power Pool (WAPP), a regional organization dedicated to fostering greater cooperation in the region's power sector and interconnection among countries to enhance energy security.[16]

SMALL HYDROPOWER OVERVIEW

The definition of small hydropower (SHP) in Sierra Leone follows that of the ECOWAS Small-Scale Hydropower Programme's, which defines SHP as hydropower with installed capacity of up to 30 MW.[16] For the purposes of this chapter, the up to 10 MW definition of SHP will be used. The country's installed capacity for SHP up to 10 MW stood at approximately 12 MW in 2020, coming from eight plants (Table 3).[7] According to the 2017 ECREEE report, Sierra Leone has 639 MW of theoretical potential for SHP up to 10 MW, including 140 MW of pico-, micro- and mini-hydropower and 499 MW of SHP of 1–10 MW capacity.[17] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed capacity slightly decreased based on the available data, whereas the potential has remained unchanged (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Sierra Leone (MW)**

RENEWABLE ENERGY POLICY

The Government of Sierra Leone has drafted a number of policies for the creation of an enabling regulatory framework for the development of off-grid renewable energy systems, including the 2009 Energy Policy and the 2016 Energy Efficiency Policy. Specifically, these policies aim to attract private sector investment in the electricity sector, ensure the financial independence and commercial viability of EDSA as well as improve the transparency, predictability and financial viability of the electricity sector.[22]

A major barrier to the penetration of off-grid renewable energy systems in Sierra Leone is the lack of financial inclusion. In 2017, approximately 80 per cent of the population did not have an account with a formal financial institution or a mobile money service provider, compared to an average of 57 per cent in Sub-Saharan Africa. As a way to increase financial inclusion in the country, the Bank of Sierra Leone launched a National Strategy for Financial Inclusion (NSFI) in 2017.[22]

Currently, the Government has several objectives regarding development and renewable energy, which are set forth in the Renewable Energy Policy of Sierra Leone and the National Renewable Energy Action Plan (NREAP) of 2015. Some of the targets include:

- Increasing installed renewable energy capacity, reaching 659 MW by 2020 and 1,229 MW by 2030;
- Increasing access to renewable energy via off-grid solutions including mini-grids;
- Increasing the number of households with solar heating systems.

In order to achieve the set renewable energy goals, the Government of Sierra Leone has been benefiting from financial assistance from the United Kingdom Foreign, Commonwealth and Development Office (FCDO) and the Government of Japan. These countries contributed an estimated USD 700,000 and USD 55,000, respectively, in 2019, for the development of mini-grid electricity systems in Sierra Leone. The United Nations Office for Project Services (UNOPS) contributed to the country's efforts in relation to renewable energy in the form of grants, with an aim of accelerating demand and improving rural energy-reliant economic opportunities and productive use of equipment and services.[23]

Sierra Leone, as a member country of the ECOWAS, is committed to achieving universal electricity access by 2025 through the ECOWAS Regional Renewable Energy Policy for the period of 2015–2030. Under the Sustainable Energy for All (SEforAll) Country Action Agenda, the Government of Sierra Leone also aims to reach a 10 per cent share of the population with access to electricity through off-grid systems powered by renewable energy by 2030.[22]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Precipitation variability is expected to increase in Sierra Leone as a consequence of climate warming. As SHP plants in the country are mostly without seasonal storage possibilities, the down-times of the plants are expected to increase due to extended dry spells. Furthermore, natural hazards are likely to increase with climate change and therefore floods, rock falls and landslides will negatively affect SHP plants.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

SHP development in Sierra Leone is hindered by:

- Funding: There is a lack of sufficient government funding for SHP development;
- Capacity building: There are not enough higher learning institutions in Sierra Leone that focus on teaching the skills necessary to operate and maintain SHP plants. There is also a lack of hydrology departments at local universities which translates into a lack of sufficient local technical experts;
- Manufacturing: All equipment necessary for the operation of an SHP plant needs to be imported as there are no local manufacturers;
- Electricity tariffs: The high electricity tariffs in the country deter private investors;
- Demand: There is low demand for electricity in the country as it suffers from a lack of sufficient financial inclusion for its population. Most citizens would be unable to afford the high electricity tariffs and are not registered with any formal financial institution.[22]

SHP development in Sierra Leone is enabled by:

- External assistance: As solar power development benefits from financial support from the international donors, this is an encouraging sign for future endeavours into the overall renewable energy sector;
- Potential: Sierra Leone has considerable hydropower potential;
- Openness to foreign investment: The country is open to foreign investment for the development of the energy sector.[22,24]

Togo

Davy Rutajoga, International Center on Small Hydro Power (ICSHP)

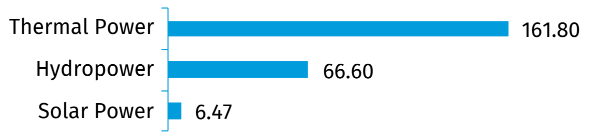
KEY FACTS

Population	8,278,737 (2020)[1]
Area	56,600 km^2 [2]
Topography	The topography of Togo consists of gently rolling hills, shallow valleys and two large alluvial plains. The Atakora Mountain Range cuts through the central part of country with natural forests and savannah landscapes. The northern part of the country, known as the Dry Sudanian Savannah, is home to the Oti River as well as a large national park. The southern regions are characterized by patchworks of cropland and savannahs. The coastal plains, or the fluvial-lagoon zone, is characterized by swamps and lagoons.[3]
Climate	Togo has a tropical climate, with two rainy seasons in the south and one in the north. In the humid south, the rainy seasons occur from mid-April through June and again from mid-September through October. In the north, the rainy season occurs from June to the end of September and the rest of the year enjoys the warm and dry harmattan (dusty wind). Mean annual temperatures in the north vary between 17 °C and 41 °C, while the south is more stable with an average annual temperature of 27 °C.[4,5]
Climate Change	Togo is affected by global warming. The mean annual temperature has increased by 1.1 °C since 1960, at an average rate of 0.24 °C per decade. The number of hot days between 1960 and 2003 has increased by 16 per cent and heatwaves have become more common. Precipitation in Togo has been decreasing at an average of 2.4 per cent per decade and no increase in heavy rainfall events have been observed.[5]
Rain Pattern	The southern coastal zone receives approximately 890 mm of annual precipitation and is the driest region. The highest amount of precipitation in the country, 1,800 mm, is received by the south-western region. In the north, precipitation averages 1,150 mm in the rainy season. The mean annual precipitation in Togo is 1,176.5 mm.[4,5]
Hydrology	Togo is endowed with many lagoons, the largest of which is Lake Togo which is also the country's largest body of inland water. More than half the length of the country is traversed by the Mono River, which flows from north to south before flowing into the Gulf of Guinea. The torrential river's intake fluctuates greatly, from an annual average of 99.6 m^3/s to 4.8 m^3/s in the dry season. The Oti River, in the north, drains into the Volta River, which flows to the north-west.[6]

ELECTRICITY SECTOR OVERVIEW

The main sources of electricity in Togo are thermal power and hydropower. In 2019, thermal power accounted for 67 per cent of total production, which amounted to 647 GWh, and hydropower accounted for almost 32 per cent. Production from solar power plants accounted for 9 GWh, or approximately 1 per cent of the total electricity produced (Figure 1).[7]

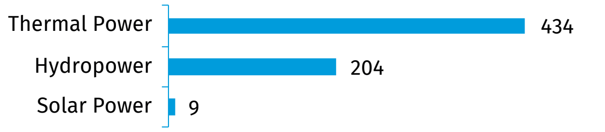
Figure 1. **Annual Electricity Generation by Source in Togo in 2019 (GWh)**



Source: IRENA[7]

In Togo, electricity is supplied mainly through the interconnected Electricity Community of Benin (CEB) and the local power system of the state-owned utility Electricity Energy Company of Togo (CEET). CEB consists of a 20 MW gas turbine in Lomé and a 65 MW hydropower plant in Nangbeto for a combined installed capacity of 85 MW. CEET owns a system of 143.4 MW of installed capacity, including a 1.6 MW hydropower plant in Kpimé and 100 MW (LFO, HFO, gas) of capacity owned by the CEET and exploited by the independent power producer (IPP) Contour Global Togo S.A under a licence. The isolated grid contributes an additional 6.47 MW of installed solar capacity. The total installed electricity capacity in 2020 was thus 234.87 MW, of which thermal power, hydropower and solar power accounted for approximately 69 per cent, 28 per cent and 3 per cent, respectively (Figure 2).[8]

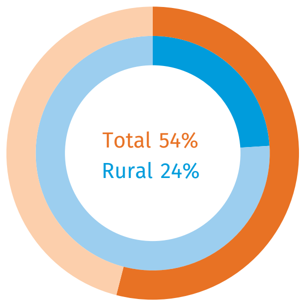
Figure 2. **Installed Electricity Capacity by Source in Togo in 2020 (MW)**



Source: ARSE[8]

In 2020, the total electrification rate in Togo was 54 per cent, with 24 per cent rural access (Figure 3).[9,10]

Figure 3. **Electrification Rate in Togo in 2020 (%)**



Source: World Bank[9,10]

Table 1. **Electricity Consumption by Sources in Togo in 2020**

Consumer category	*Electricity consumed (%)*
Commercial and industrial sector	57.4
Residential sector	32.6
Administration and public Services	10.0

Source: ARSE[8]

In Togo, the electricity sector is regulated by the Regulation Authority of the Electricity Sector (ARSE), which is also responsible for advising the Ministry of Mines and Energy on electricity tariffs, among other duties. Since 2011, the electricity tariffs on the Togolese territory are fixed through the ministerial decree No. 019/MME/MEF/MCDAT/MPR-PDAT/MCPSP of 2010. In 2020, the tariffs ranged from 0.17 USD/kWh to 0.20 USD/kWh (Table 2).[8]

Table 2. **Electricity Tariffs in Togo in 2020**

Customer category	*Tariff, incl. taxes (USD/kWh)*
Low voltage	0.20
Medium voltage	0.17
High voltage	0.19

Source: ARSE[8]

CEET is the Government-owned utility responsible for the distribution and transmission of electricity produced in Togo both through its own power plants, power plants exploited by IPPs and shared plants with CEB. CEB is a bi-national entity established in 1968 to provide generation and transmission for both Togo and Benin and had, until 2003, a monopoly on the production and distribution of electricity for both countries.[8]

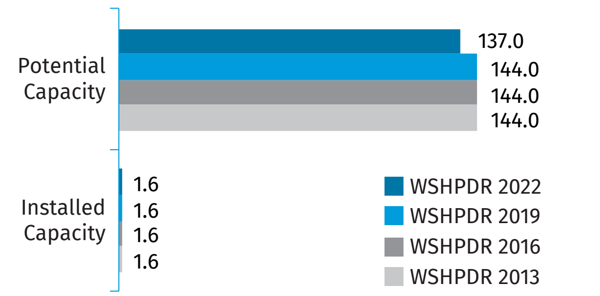
In addition to being half of the interconnected Benin–Togo grid, Togo is also a member of the Economic Community of West African States (ECOWAS) energy framework and the West Africa Power Pool (WAPP).[11]

SMALL HYDROPOWER SECTOR OVERVIEW

There is no official definition of small hydropower (SHP) in Togo. For the purpose of this chapter, SHP will include hydropower plants with an installed capacity of up to 10 MW. It should be noted that in the ECOWAS region, which Togo is part of, many countries use the ECOWAS definition of 1 MW to 30 MW of installed capacity for SHP.

There is one SHP plant in Togo, located in Kpimé, with an installed capacity of 1.6 MW. The identified SHP potential is approximately 137 MW. This identified potential differs from the potential reported in the *World Small Hydropower Development Report (WSHPDR) 2019* due to later studies conducted by the Government of Togo as indicated in the Baseline Report on Existing and Potential Small-Scale hydropower systems in the ECOWAS Region.[12] At the same time, the installed SHP capacity remained unchanged (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Togo (MW)**



Source: ECREEE,[12] *WSHPDR 2013*,[13] *WSHPDR 2016*,[14] *WSHPDR 2019*[15]

The Baseline Report on Existing and Potential Small-Scale Hydropower Systems in the ECOWAS Region was prepared by the ECOWAS for Renewable Energy and Energy Efficiency (ECREEE) in cooperation with the United Nations Industrial Development Organization (UNIDO), the Energy Sector Management Assistance Programme (ESMAP) and the Government of Liberia. The report explored the SHP potential of ECOWAS member-states and highlighted the SHP potential of Togo, under both the ECOWAS definition of SHP (up to 30 MW) and the international definition (up to 10 MW). The former definition produced an SHP potential of 206 MW and the latter 137 MW.[12]

There are numerous rivers in Togo and the Government has identified seven sites for the development of SHP with a combined potential installed capacity of 40 MW (Table 3).[16]

Table 3. **List of Selected Planned Small Hydropower Projects in Togo**

RENEWABLE ENERGY POLICY

As a member of ECOWAS, Togo adopted the National Renewable Energy Policy (NREP) and the National Energy Efficiency Policy (NEEP) that all 15 member-states adopted in 2012. In 2015, The Government of Togo combined the NREP and NEEP for a cohesive National Renewable Energy Action Plan (NREAP 2015–2020–2030), which outlines the legal framework for electricity generation from renewable energy sources, both for own and commercial use. The NREAP addresses all sources of renewable energy, including wind power, solar power, thermal power, tidal power and hydropower and defines incentives for developers of renewable energy projects, such as tax incentives. The policy was developed by the Ministry of Mines and Energy in cooperation with CEET, the Togolese Rural Electrification and Renewable Energy Agency (AT2ER), ARSE, ECREEE, the German Agency for International Cooperation (GIZ) and the Governments of Austria and Spain.[17]

In the NREAP, the Government of Togo has several objectives regarding the development of renewable energy. Some of the targets include:

- Develop solar power capacity and increase its share in the final energy consumption to 10 per cent by 2030;
- Develop SHP in rural areas and ensure minimal environmental impact from SHP construction and maintenance;
- Attract private sector investment in hydropower;
- Develop bioenergy and promote consumption, particularly in rural areas, as an alternative source of energy;
- Develop a comprehensive database on renewable energy potential in Togo.[17]

The targets set in the NREAP were formulated to fulfil the goals of universal electrification and increase in installed renewable energy capacity to 364 MW by 2030. In addition to the specific targets, the Government of Togo aims to promote education and awareness of environmental protection and the importance of renewable energy. The Government of Togo also aims to involve local populations in all aspects of renewable energy development, including rural population involvement in the construction and development of SHP.[17]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

SHP plants are regulated by the same legislation as larger hydropower projects. The main legislation and regulation documents in Togo concerning hydropower projects are:

- Decree No. 63-12 (1963) on the creation of the Electricity Energy Company of Togo;
- Law No. 2000-012 (2000) on the organization and function of ARSE;
- Decree No. 2019-021 (2019) that sets the licensing for production, transmission and commercialization of renewable energy.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Precipitation variability is expected to increase in Togo as a consequence of climate warming. As the only SHP plant in the country is mostly without seasonal storage possibilities, the down-times of the plant are increasing due to extended dry spells. Furthermore, natural hazards are likely to increase with climate change and, therefore, floods, rock falls and landslides will negatively affect existing and prospective SHP plants.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The development of SHP in Togo is mainly hampered by:

- Non-liberalized energy sector might deter prospective investors;
- Lack of sufficient and relevant rules and regulations within the energy sector such as standardized power purchase agreements and power purchase tariffs;
- Higher initial costs for hydropower investment than diesel generators;
- Lack of sufficient international funding for SHP driven by the lack of successful SHP projects that would inspire confidence in investors;
- Lack of manufacturing of equipment essential for SHP construction and maintenance in the country.

Enablers for SHP development in Togo include:

- Specific mention of SHP and its importance for rural electrification in national renewable energy strategy documents such as NREP and NREE;
- The commitment by the Government to exploit the country's SHP potential. Plans to build SHP plants at Danyi-Konda, Baghan and Landa-Pozanda were in mo-

tion as of 2022;
- Significant potential for SHP development due to numerous rivers found in the country;
- Plans to promote private sector investment in SHP as outlined in the country's national renewable energy strategy.

2. Americas

2.1. Caribbean

Countries: Cuba, Dominica, Dominican Republic, Grenada, Guadeloupe, Haiti, Jamaica, Puerto Rico, Saint Lucia, Saint Vincent and the Grenadines

INTRODUCTION TO THE REGION

The electricity sectors of countries in the Caribbean are heavily reliant on thermal power for electricity generation, with renewable energy sources (RES) playing a supplementary role. Compared to other countries in the region, both the Dominican Republic and Guadeloupe have a highly diversified energy mix, although fossil fuels still predominate. Alongside wind power, solar power and hydropower, RES in the region are represented by biomass and geothermal power plants.

The role of hydropower in the region is limited due to environmental and economic factors. Only Cuba, the Dominican Republic and Haiti employ large hydropower plants, while Grenada and Saint Lucia have no hydropower capacity of any kind. In other countries in the region, all existing hydropower capacities are represented by small hydropower (SHP).

Access to electricity is at or near 100 per cent across most countries in the region with the exception of Haiti. However, seasonal extreme weather in the form of hurricanes and associated floods frequently interfere with power grids and plant infrastructure across the region, causing major disruptions to electricity access. Earthquakes have also caused widespread damage to electricity infrastructure, particularly in Haiti and Puerto Rico.

The role of the state in the electricity sectors of countries in the Caribbean varies significantly. At one end, the electricity sector of Cuba is fully state-owned. In Guadeloupe the sector is dominated by a French company where the Government of France has a controlling stake. In Saint Vincent and the Grenadines, a state-owned company operates the electricity sector across most of the country with the exception of one island, and the electricity sector of Haiti is also dominated by a state-owned company. In Puerto Rico, a state-owned company controls the largest share of generation assets, while transmission and distribution have recently been privatized. In the Dominican Republic, the electricity sector has a significant private sector and state involvement, although state-owned entities control the transmission grid and all hydropower assets. In Dominica, Grenada, Saint Lucia and Jamaica, the electricity sectors have been largely privatized.

An overview of the electricity sectors of the countries in the region is provided in Table 1.

Table 1. **Overview of the Caribbean**

Country	*Total population (million people)*	*Electricity access, total (%)*	*Electricity access, rural (%)*	*Total installed capacity (MW)*	*Electricity generation (GWh/year)*	*Hydropower installed capacity (MW)*	*Hydropower generation (GWh/year)*
Cuba	11	100	100	6,508	20,700	64	125
Dominica	0.1	100	100	27	97	7	19

REGIONAL SMALL HYDROPOWER OVERVIEW

The most commonly-used official definition of SHP in the Caribbean is up to 10 MW, and is adhered to by Dominica, the Dominican Republic, Guadeloupe, and Saint Vincent and the Grenadines. In other countries of the Caribbean, no official SHP definition exists. In Jamaica, which lacks an official definition of SHP, the up to 10 MW definition is commonly used by industry professionals, while in Cuba, the up to 5 MW definition established by the Latin American Organization of Energy (OLADE) is used on an unofficial basis.

A comparison of installed and potential SHP capacities in the region is provided in Table 2.

Table 2. **Small Hydropower Capacities by Country in the Caribbean (MW)**

Country	*Local SHP definition*	*Installed capacity (local def.)*	*Potential capacity (local def.)*	*Installed capacity (≤10 MW)*	*Potential capacity (≤10 MW)*
Cuba	N/A	N/A	N/A	21.0	77.0
Dominica	Up to 10 MW	6.6	N/A	6.6	6.6*
Dominican Republic	Up to 10 MW	59.7	N/A	59.7	59.7*
Grenada	N/A	N/A	N/A	0.0	7.0
Guadeloupe	Up to 10 MW	11.6	33.0	**11.6**	33.0
Haiti	N/A	N/A	N/A	6.8	37.6
Jamaica	N/A	N/A	N/A	30.6	76.2
Puerto Rico	N/A	N/A	N/A	39.3	43.9
Saint Lucia	N/A	N/A	N/A	0.0	2.7
Saint Vincent and the Grenadines	Up to 10 MW	5.7	7.5	5.7	7.5
Total	-	-	-	**181.4**	**351.1**

Source: *WSHPDR 2022*[1]

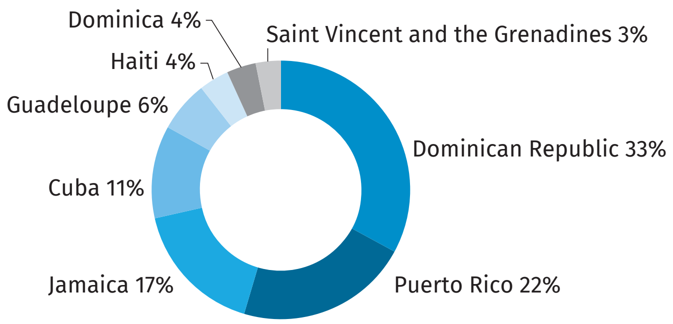
Note: *Based on installed capacity.

The total installed capacity of SHP of up to 10 MW in the Caribbean is 181.4 MW, while estimated potential capacity is 351.1 MW. Relative to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed capacity increased by 2 per cent, largely due to a nearly two-fold increase in the installed SHP capacity of Jamaica. Meanwhile, the installed capacities of several countries including Cuba, Haiti, Puerto Rico, and Saint Vincent and the Grenadines have been revised downwards on the basis of more accurate data. The total potential SHP capacity of the region increased by 18 per cent as a result of updated feasibility studies of potential sites as well as a reassessment of available data.

SHP fills an important niche in the energy mix of the Caribbean region, in part because the geographical and hydrological characteristics of many island countries and the importance of tourism in the region put constraints on the use of large hydropower. SHP accounts for all installed hydropower capacity in Dominica, Guadeloupe, Jamaica, Puerto Rico, and Saint Vincent and the Grenadines. In Cuba approximately a third of all installed hydropower capacity consists of SHP. At the same time, recent development in the SHP sector in the Caribbean has been very limited and further SHP development also faces significant barriers. A major reason for this is the high variability in rainfall and runoff typical for the region and the susceptibility of SHP to extreme weather events, and the consequent focus of many Caribbean countries on other RES.

The national share of regional installed capacity for SHP of up to 10 MW by country is displayed in Figure 1, while the share of total SHP potential utilized by countries in the region is displayed in Figure 2.

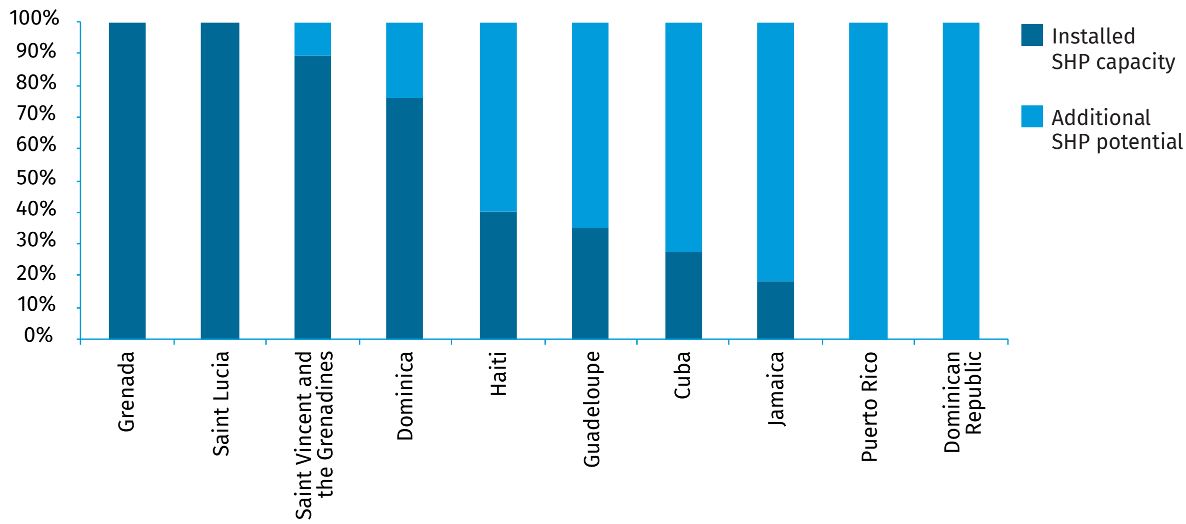
Figure 1. **Share of Regional Installed Capacity of Small Hydropower up to 10 MW by Country in the Caribbean (%)**



Source: *WSHPDR 2022*[1]

Note: Saint Lucia and Grenada not included due to lack of SHP.

Figure 2. **Utilized Small Hydropower Potential up to 10 MW by Country in the Caribbean (%)**



Source: *WSHPDR 2022*[1]

Note: No estimate of potential capacity is available for Dominica and the Dominican Republic, therefore SHP potential in these countries is assumed to be fully utilized.

Cuba has an installed capacity of 21 MW for SHP up to 10 MW, while potential capacity is estimated at 77 MW, indicating that 27 per cent has been developed. Cuba has over 170 SHP plants, of which 32 are currently non-operational due to water supply issues or disrepair. The most recent new SHP plant was commissioned in 2018, while another plant was refurbished in 2019. There were two additional SHP projects under construction as of 2021.

There are three SHP plants of up to 10 MW in **Dominica**, with a total installed capacity of 6.64 MW. The potential capacity of Dominica has not been assessed, so all known capacity is fully developed. One of the SHP plants in the country has been out of operation since 2017 as a result of hurricane damage, and the bidding process for its rehabilitation was launched in early 2022.

The installed capacity of SHP of up to 10 MW in the **Dominican Republic** is 59.7 MW provided by 16 state-owned SHP plants equipped with 22 individual power blocks, and 60 community-owned micro-hydropower plants. There is no reliable estimate of SHP potential in the country, thus, all known potential is considered fully developed. Recent SHP development in the country has been mainly carried out with the support of the Global Environmental Facility (GEF) Small Grants Programme and has focused on the construction of micro-scale plants for the benefit of rural communities. Ten additional micro-scale SHP projects are under construction.

Grenada has no hydropower capacity of any kind. The potential capacity of SHP up to 10 MW is estimated at 7 MW, although the estimate is based on a study conducted in 1981. Several SHP projects have been initiated in recent years but have not been completed and their current status is unknown.

Guadeloupe has a total installed capacity of 11.6 MW for SHP of up to 10 MW, provided by 16 plants. The potential SHP capacity is estimated at 33 MW, indicating that 35 per cent has been developed. However, the development of remaining untapped potential capacities is constrained by environmental considerations and the location of many potential sites inside protected areas. No new SHP construction has taken place in the country since 2016.

The installed capacity of SHP up to 10 MW in **Haiti** is 6.81 MW, provided by eight plants, while potential capacity is estimated at 37.6 MW, indicating that 18 per cent has been developed. No new SHP construction has taken place in the country in recent years and installed capacity has gradually decreased due to ageing equipment and lack of maintenance. Thirty-six potential SHP sites have been identified in the country.

Jamaica has an installed capacity of 30.6 MW for SHP of up to 10 MW, provided by eight SHP plants. The potential capacity for SHP of up to 10 MW is estimated at 76.2 MW, indicating that 40 per cent has been developed. The country's SHP fleet is fairly old and no new additions have been made since 2014, with the recent reported increase in installed capacity being a result of the inclusion of previously excluded plants. Thirteen potential SHP sites have been identified and the country has explicitly adopted a policy of exploring options for SHP construction at locations with the potential to host large hydropower plants.

The installed capacity of SHP of up to 10 MW in **Puerto Rico** is 39.3 MW, while potential is estimated at 43.9 MW, indicating that 89 per cent has been developed. There are seven operational SHP plants in the country, although with four of these plants inactive as of 2021, the available capacity has been reduced to 23.8 MW. The main potential opportunities for further SHP development are in micro-scale hydropower projects, as other potential hydropower sites have been largely developed.

Saint Lucia has no hydropower capacity of any kind, as the country's only formerly-operational mini-hydropower plant is in a state of severe disrepair following damage from extreme weather. A potential capacity of 2.68 MW has been identified in previous studies, but there are no ongoing SHP projects in the country or any specific plans for the development of the SHP sector.

In **Saint Vincent and the Grenadines**, the installed capacity of SHP of up to 10 MW is 5.7 MW, while estimated potential capacity is 7.5 MW, indicating that 76 per cent has been developed. There are three SHP plants in the country, but their available capacity fluctuates considerably during the dry season. Refurbishment of two plants was carried out in 2016 and 2018. There are proposals for the construction of an additional SHP plant of 1.2 MW, but no concrete progress has been made.

Changes in the installed SHP capacities of the countries in the region compared to the previous editions of the *WSHPDR* are displayed in Figure 3.

Figure 3. **Change in Installed Capacity of Small Hydropower up to 10 MW from *WSHPDR 2013* to *WSHPDR 2022* by Country in the Caribbean (MW)**

Climate Change and Small Hydropower

The region experiences increased winter precipitation and decreased summer precipitation during the El Niño Southern Oscillation (ENSO) phase. These seasonal differences are expected to become even more pronounced as a result of climate change. The increase in frequency and intensity of extreme events exposes SHP infrastructure to damage.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The barriers to SHP development in **Cuba** include a lack of technical capacity in planning SHP projects and the manufacture of necessary components, limited financial resources and low utilization of existing capacities due to environmental limitations. However, a substantial share of the country's SHP potential remains untapped and government policies are supportive of development in the sector, particularly with regard to foreign investment.

The main barriers to SHP development in **Dominica** include a lack of incentives, a lack of data on SHP potential, issues with land acquisition from private owners and limitations on hydropower development in general due to the importance of eco-tourism in the country. Additionally, the Government has been exploring geothermal power as a prospective RES and has shown comparatively little interest in additional SHP development. However, geothermal power projects are considered to have a higher development cost relative to SHP and it is possible that SHP development will be prioritized again in the future, given the country's experience with this form of renewable energy.

SHP development in the **Dominican Republic** faces a number of challenges including increasing impacts from climate change, which affect water supply and cause damage to SHP infrastructure, a lack of data on SHP potential, lengthy administrative procedures and lack of private sector engagement. However, some studies on the potential of specific SHP sites are available. The SHP sector in the country is well-organized and can lean on decades of experience and local expertise, as well as take advantage of established international financing opportunities. The active development of micro-scale hydropower is expected to continue into the foreseeable future.

In **Grenada**, the lack of interest in SHP on the part of the Government is one of the main barriers to SHP development in the country, along with the lack of up-to-date studies of SHP potential. However, the untapped SHP potential could serve as an additional source of renewable energy to meet the country's declared clean energy goals and reduce dependence on fossil fuels.

The main obstacle to SHP development in **Guadeloupe** are the environmental restrictions that constrain the implementation of additional projects. The country has consequently focused on the development of other RES, in particular solar power, wind power and geothermal power. One possible avenue for further SHP development in the country that would avoid environmental impacts is the optimization of exiting SHP capacities.

SHP development in **Haiti** is hampered by a lack of a legal framework for private investment in the energy sector as well as a lack of coordination between government agencies and ministries, in addition to a lack of funds and limited reach of the country's transmission grid. However, much of the country's identified SHP potential remains untapped and represents an important potential source for electricity generation in a country with the region's lowest rate of electricity access.

Barriers to SHP development in **Jamaica** include the high cost and perceived complexity of construction, institutional barriers and hydrological variability. At the same time, the country possesses considerable untapped SHP potential and the Government's interest in SHP as opposed to large hydropower is a potential driver of future SHP development, both in terms of new construction and modernization of existing capacities.

The main barrier to further SHP development in **Puerto Rico** is the high degree of utilization of the country's existing potential SHP capacities, leaving few remaining undeveloped sites. Severe weather and water shortages are also important barriers. The main opportunities for SHP development in the country lie in micro-scale projects and the refurbishment of existing SHP plants, which has been identified as a priority direction by a government study in 2021. An additional enabler is the availability of support for RES in the form of subsidies.

Barriers to SHP development in **Saint Lucia** include the extremely limited SHP potential and the lack of funding opportunities specifically aimed at SHP projects. However, SHP could serve as an additional source of renewable energy and reduce the country's dependence on fossil fuels if efforts were directed at repairing the existing damaged mini-hydropower plant and develop identified potential sites.

The main barrier to SHP development in **Saint Vincent and the Grenadines** is the variability of river flow throughout the year that complicates the implementation of new SHP projects and also reduces the available capacity of existing plants. Very little SHP potential exists on the country's smaller islands and plans for the development of RES have focused on solar power and geothermal power. At the same time, all RES projects including SHP have access to feed-in tariffs (FITs) and financing for renewable energy development in the country is Available at international institutions including the GEF, the World Bank, the International Renewable Energy Agency and others.

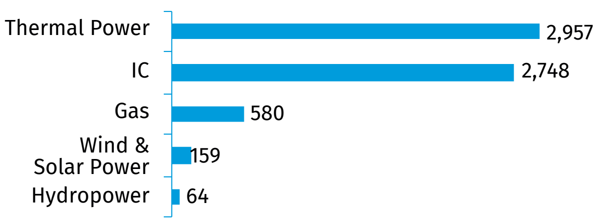
KEY FACTS

Population	11,193,470 (2019)[1]
Area	109,884.01 km^2 [2]
Topography	Approximately a quarter of the territory of Cuba is mountainous with hills dotted across the island, alternating with plains, and four main mountain ranges: the Guamuhaya in the centre (also known as mountains of the Escambray), the Guaniguanico in the west, the Nipe-Sagua-Baracoa in the north-east and the Maestra in the south-east. The Maestra is the largest mountain range and home to Pico Real del Turquino, the country’s highest peak at 1,974 metres.[2]
Climate	The climate is semi-tropical or temperate, except in the mountains. The average minimum temperature is 21 °C and the average maximum is 30 °C. The average relative humidity is 79 per cent. Coas tal areas are relatively cooler due to trade winds and sea breezes. The eastern coast is often hit by hurricanes from June to November.[3,4]
Climate Change	Droughts are common in the region of Eastern Cuba. However, due to climate change effects, the western and central regions have also started to be heavily affected by droughts.[3,4]
Rain Pattern	The rainy season in Cuba lasts from May to October. The average annual precipitation is 1,444 mm, with the mountainous areas on average receiving more than 1,800 mm a year and most of the lowland regions ranging from 900 to 1,400 mm. The area around Guantanamo Bay in the south-east receives less than 650 mm of precipitation a year.[3,4]
Hydrology	The topography and climate of the island result in short rivers with reduced flows. The longest river is the Cauto (249 km long), flowing westwards north of the Maestra. Other major rivers include the Sagua la Grande, the Zaza, the Caonao and the San Pedro. The Toa River (116,2 km), located in the provinces of Holguín and Guantanamo, has the largest volume of flow in the country.[3,4]

ELECTRICITY SECTOR OVERVIEW

In 2019, annual electricity generation in Cuba was approximately 20,700 GWh (Figure 1). Fossil fuel-based thermal power plants contributed approximately 77 per cent, including gas-powered turbines and other thermal power plants from industries (mainly biomass from the sugar cane industry). Grid-connected internal combustion (IC) generators contributed 21 per cent, while hydropower and other renewable energy sources (including wind and solar power) contributed slightly less than 2 per cent combined. Total renewable electricity in 2019 amounted to 894 GWh (4 per cent), including 519 GWh from biomass.[5]

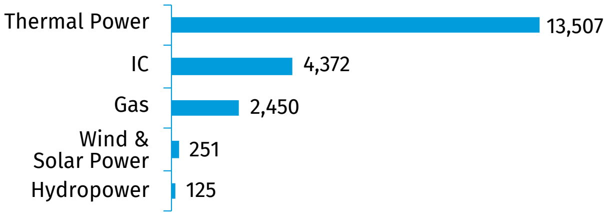
Figure 1. **Annual Electricity Generation by Source in Cuba in 2019 (GWh)**



Source: ONEI[5]

In 2019, installed capacity totalled 6,507.8 MW, with approximately 46 per cent from thermal power plants, including 7 per cent from generators operated by the Ministry of Energy and Mines and the Group of Sugar Industries (AZCUBA). IC power generators contributed 42 per cent, 9 per cent was from gas turbines and 2 per cent from solar photovoltaics (PV) and wind power. Only 1 per cent of installed capacity was from hydropower (Figure 2).[5]

Figure 2. **Installed Electricity Capacity by Source in Cuba in 2019 (MW)**



Source: ONEI[5]

Cuba achieved 100 per cent electrification rate in 2018.[5] Total electricity consumption reached 20,703.2 GWh in 2019, with the residential and public sectors having consumed approximately 45 and 39 per cent, respectively. The gross generation index stood at 1.8 MWh per citizen. Losses amounted to approximately 16 per cent.[5]

The electricity sector in Cuba is fully public, owned by the Electric Union of Cuba (UNE). UNE is part of the Ministry of Energy and Mines (MINEM) and is the main entity responsible for the generation, transmission and distribution of electricity in the country, with the exception of the electricity generated by sugar cane biomass, which is owned by AZCUBA. The National Institute for Hydraulic Resources (INRH) is the regulatory authority responsible for the management of water resources. However, hydropower plants are owned by UNE, via a subsidiary, the Renewable Energy Sources Company (EMFRE). Water use for hydropower generation is subordinated to irrigation and population supply. Furthermore, reservoirs are not built exclusively for electricity production.[5,6,7]

Since 2005, the electricity sector of Cuba has undergone numerous reforms with a new energy development strategy known as the Energy Revolution started in 2006. Notably, the key features of the strategy include the promotion of distributed generation, rehabilitation of electric grids, energy saving and energy education and the promotion of renewable energy sources. The focus of the National Electric System (SEN) has been placed on increasing the use of renewable energy, liquid natural gas and biomass to gradually decrease the share of oil-based thermal power plants.[4,5]

In recent years, the share of combined cycle and IC generators in the country's energy mix has experienced a rise as a result of the efforts to move away from a concentrated system composed of large thermal power plants towards a distributed generation system. The reduced concentration of the country's generation capacity in large thermal power plants has also mitigated the risks posed to the system by hurricane damage. Furthermore, the efforts in achieving a distributed system reduced the consumption of fossil fuels as the energy efficiency of IC generators is higher than that of large thermal power plants.[4] The specific fuel consumption of all power plants in 2018 was 257.7 grams of conventional fuel per kilowatt-hour (g/kWh), however thermal fuel consumption stood at 276.1 g/kWh.[5]

Since January 2021, new electricity tariffs have been introduced for households and the non-residential sector, as part of the country's ongoing process of monetary unification. In particular, electricity tariffs have increased exponentially, with tariffs depending on monthly consumption (Table 1).[8,9] The new average price is approximately three times higher than in the old tariff system, under which 97.8 per cent of the customers consumed up to 500 kWh. The increase of electricity tariffs is directly related to the devaluation of the Cuban Peso, given that the electricity supply of Cuba is heavily dependent on energy imports.[8]

Table 1. **Electricity Tariffs in Cuba in 2021**

Consumption (kWh)	*Price (CUP/kWh (USD/kWh))*	*Consumption (kWh)*	*Price (CUP/kWh (USD/kWh))*
0–100	0.33 (0.01)	501–600	9.20 (0.38)
101–150	1.07 (0.04)	601–700	9.45 (0.39)
151–200	1.43 (0.06)	701–1,000	9.85 (0.41)
201–250	2.46 (0.10)	1,001–1,800	10.80 (0.45)
251–300	3.00 (0.13)	1,801–2,600	11.80 (0.49)
301–350	4.00 (0.17)	2,601–3,400	12.90 (0.54)
351–400	5.00 (0.21)	3,401–4,200	13.95 (0.58)
401–450	6.00 (0.25)	4,201–5,000	15.00 (0.63)
451–500	7.00 (0.29)	>5,000	20.00 (0.84)

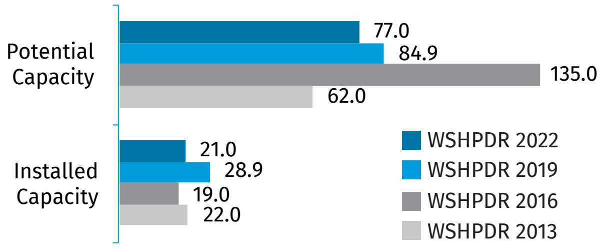
SMALL HYDROPOWER SECTOR OVERVIEW

Cuba has more than one hundred years of experience in the use of hydropower for electricity generation, which was one of the most utilized renewable energy technologies in the first half of the 20th century. Currently, hydropower is the third-largest renewable energy source in Cuba by installed capacity.

There is no official definition of small hydropower (SHP) in Cuba, but unofficially Cuba assumes the terminology of the Latin American Organization of Energy (OLADE) that is less than 5 MW of installed capacity.[10,11] However, for the purposes of this report, a definition of SHP as hydropower plants with an installed capacity of less than 10 MW will be followed.

The current installed operational hydropower capacity in Cuba is 64 MW, with 43 MW from the Hanabanilla hydropower plant and 21 MW from SHP, in accordance with the up to 10 MW definition.[5,12] In comparison with the data from the *World Small Hydropower Development Report (WSHPDR) 2019*, the country's installed SHP capacity has decreased by over 27 per cent while the estimate SHP potential has decreased by 9 per cent, due to access to more accurate data (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Cuba (MW)**



Source: *WSHPDR 2019*,[4] ONEI,[5] *WSHPDR 2013*,[13] *WSHPDR 2016*[14]

As of 2020, there were a total of 170 hydropower plants in Cuba. Of these, 138 were operational SHP plants, including 41 SHP plants connected to the SEN and 97 SHP plants (70 per cent) operating in isolation from the SEN, offering service to 8,486 isolated households.[12,15] Currently, 32 SHP plants are identified as non-operational, of which 25 plants lack water supply as a result of climate change and seven are in need of refurbishment.[12] The nine most productive SHP plants in Cuba are listed in Table 2. Given that some SHP plants were commissioned decades ago, they require refurbishment. For budgetary reasons, only the C. M. de Céspedes SHP plant was refurbished in 2019.

Table 2. **List of Most Productive Operational Small Hydropower Plants in Cuba**

Source: Peña Pupo & Fariñas Wong[16]

There are two SHP plants to be completed in 2021: the Alacranes SHPP (2.1 MW) in Villa Clara and the Mayarí MI SHPP (1.25 MW) in Holguín (Table 3). Furthermore, in 2020 a feasibility study of one pumped storage hydropower plant of 200 MW in Mayarí was completed.[6,15] Given that Cuba does not have major rivers or large bodies of inland water, the development of hydropower will remain focused on small-scale projects. The technical potential of hydropower in Cuba is estimated, based on preliminary studies, to be 135 MW, including 13.7 MW in channels.[15] This potential was determined by an inventory of potential sites in the 1980s. The study involved cartographic maps and precipitation measurements, with a few cases where a deep hydrological assessment was carried out. Currently, the estimated capacity of some SHP sites is being increased using hydrological assessment based on field investigations. However, the methods used were developed in Cuba in the 1980s. Thus, the current hydrological design remains weak due to the lack of local expertise in SHP. The updated estimate of SHP potential in Cuba is 77 MW, which is based on previous calculations of 56 MW of total planned capacity and the current installed capacity of 21 MW.[15]

SMALL HYDROPOWER PROJECTS AVAILABLE FOR INVESTMENT

In 2016, Cuba signed an agreement with the Kuwait Fund for Arab Economic Development (KFAED), which provided USD 30 million for the construction of 34 SHP projects with a combined capacity of 14.6 MW.[4,17,18] Furthermore, by October 2020, some contracts had been signed with a European supplier (STM Power) for the development of 10 SHP projects and supply of SHP technology. The duration of the project is seven years.[16] Table 4 provides a list of selected sites available for development or refurbishment based on full feasibility studies.

Table 4. **List of Selected Small Hydropower Sites Available for Development and Refurbishment**

Name	*Location*	*Potential capacity (MW)*	*Head (m)*	*Type of site*
Guaso	Guantánamo	1.05	190	Refurbishment

Cauto el Paso 2	Granma	0.65	6	New

Source: Peña Pupo & Fariñas Wong[16]

The Government of Cuba drew up plans in 2016 for the development of 74 SHP plants by 2030, representing over 56 MW in capacity (274 GWh), which are available for foreign investment.[19,20] This would nearly double the country's current hydropower capacity, producing an estimated 274 GWh of renewable electricity annually and offsetting up to 230,000 tonnes of CO_2 emissions.[4]

RENEWABLE ENERGY POLICY

The Government of Cuba has recognized the decisive role that renewable energy has to play in the future development of the country. The Government has aspirations to increase the share of renewable energy sources in the country's electricity generation mix to 24 per cent by 2030. This will be composed largely of biomass, wind power and solar PV, with SHP playing a lesser role.[19] The Parliament and the Council of Ministers of Cuba approved the Policy for the Prospective Development of Renewable Energy Sources and the Efficient Use of Energy for 2014–2030 in July 2014.[20] The policy aims to diversify the energy mix by taking into account the use of every renewable energy source. The policy's main objectives are:

- Reducing dependency on fossil fuels and, therefore, increasing energy independence;
- Decreasing the high consumer cost of energy derived from the cost of fuel and the low efficiency of the electricity system;
- Contributing to environmental sustainability;
- Introducing a new foreign investment law.[4,19]

In March 2018, the Government signed Law 345 on the Development of Renewable Sources and the Efficient Use of Energy.[20] The Law also makes provisions for tariff exemptions for the imports of components and equipment for renewable energy projects.[4,20]

The Cuban industry aims to be able to achieve the recovery of production of hydraulic turbines to modernize and upgrade existing SHP facilities. The priorities include the production of new horizontal turbines for micro-hydropower plants as well as the production of speed governors. In addition, the sector looks for foreign investment to strengthen the industry.[15,19] Foreign investments have already contributed to the transition and diversification of the energy mix of Cuba through projects based on solar power, wind power, hydropower, biogas and agricultural as well as industrial residuals such as sugarcane biomass.[19] There are no feed-in tariffs or renewable electricity prices in Cuba, however in the case of foreign investment, the purchase prices and electricity sale can be negotiated.[20]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

The Environmental Law (Law 81-1997) laid the foundation for the recognition of the role of renewable energy in the country's development and has been subsequently added to over the past two decades. In the protected areas, severe environmental regulations are applied, making construction in such areas practically impossible. With regard to hydropower, under Resolution 114-1990, the INRH has the competence to approve the entities (including foreign ones) that are authorized to develop a project related to water.[4,21]

Efficient and responsible management and utilization of water resources have become a national priority since the implementation of the Cuban Programme to Combat Climate Change (Programa Cubano de Enfrentamiento al Cambio Climático) of 2007, the 2012 National Water Policy (Política Nacional del Agua 2012) and Law 124-2017 on terrestrial waters.[7]

The Government of Cuba is open to investment from foreign enterprises in renewable energy projects, by means of either joint ventures with Cuban enterprises or fully-foreign investment.[19] However, Foreign Investment Law (Law 118-2014, replacing Law 77-1995) does not include specific legislation for renewable energy sources, as Law 345 or Decree Law 327 do.[21,22] Law 118 and Decree Law 327 establish the procedures for any type of investment in Cuba. According to Decree Law 327, the investor should make a request to the Institute of Physical Planning, which in its turn will provide an answer within a 60-day period, specifying the technological and environmental regulations that the investor is expected to comply with. Once these requirements are satisfactorily met by the investor a certificate of licences for construction is granted.[20]

FINANCIAL MECHANISM FOR SMALL HYDROPOWER PROJECTS

Cuba is one of the few countries in the world that does not have membership in any major international finance institutions, including the International Monetary Fund (IMF), the World Bank and the Inter-American Development Bank (IDB).[4] However, some loans have been guaranteed by international institutions as well as countries with which Cuba has a longstanding trade tradition and relationship.[15] In January 2018, the Cuba Sustainable Energy Forum was held in Havana, which was attended by participants from the European Union, international energy companies and the private sector. Attracting foreign investment is critical for the Government's goal of achieving USD 3.5 billion of investment into the energy sector. Furthermore, Cuba has been strengthening its engagement with the International Renewable Energy Agency (IRENA) through the SIDS Lighthouses Initiative.[4,23]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Droughts, especially those associated with El Niño episodes, have caused enormous impacts during the past 15 years and are projected to severely affect the Caribbean region in the future. For this reason, specific solutions must be implemented to reduce the risk of a lack of electricity production by SHP plants as foreseen in the National Plan to Confront Climate Change, known as Tarea Vida (Project Life).[24] On the other hand, it is important to stress that half of the country's hydropower potential lies in protected regions with a high biodiversity value, one of the reasons why hydropower has not been developed in Cuba on a larger scale until today.[25]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The SHP sector has a tradition of over one hundred years in Cuba. It is also currently growing despite the existing financial and environmental limitations. There is a well identified potential for the construction of new SHP plants. The existence of a law on foreign investments and of a renewable energy policy constitute an advantage for the further development of SHP in Cuba.

The barriers that have limited the use of SHP in Cuba are similar to those that have limited the development of other renewable energy sources in the country. These technical, social, institutional, economic, financial and regulatory barriers include:

- Lack of advanced technologies to further study hydropower potential;
- Limited financial resources;
- Limited technical capacity to carry out feasibility studies;
- Limited ability of the national industry to ensure the availability of equipment, components and spare parts;
- Low usage of the existing production capacities;
- Limited scientific and technological capacity of the hydropower sector;
- Insufficient maintenance of existing facilities.[26,27]

The main enablers for SHP development in Cuba are as follows:

- Well studied potential hydropower projects available for foreign investment;
- Existence of Government renewable energy plans;
- Existence of legislation and regulations supporting foreign investment.

Dominica

Davy Rutajoga, International Center on Small Hydro Power (ICSHP)

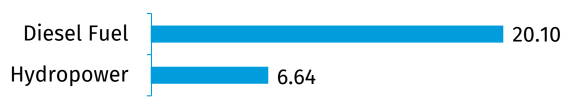
KEY FACTS

Population	71,991 (2020)[1]
Area	751 km^2 [2]
Topography	Considered the largest and most northerly of the Windward Islands, the country is also part of the rugged Lesser Antilles volcanic arc. An island of volcanic origin, the terrain is very rugged with some active volcanoes and a number of hot springs. Mountains cover both the northern and southern interior, with a small plain in the centre. Its vegetation is lush and green, with dense forests and a tropical flora on steep slopes. The slopes in Dominica vary in elevation from 300 to 1,400 metres above sea level. Its highest peak is Morne Diablotins situated in the northern interior of the island, which reaches 1,447 metres.[2]
Climate	Dominica has a tropical wet climate, characterized by heavy rainfall and warm temperatures. Temperatures rarely fluctuate and the average temperature throughout the year is 27 °C near the coast and in high altitudes it is cooler with an average of 20 °C. During the summer months of July and August days are hot and humid with temperatures typically around 32 °C.[2,3]
Climate Change	An island state in the Caribbean, Dominica is especially vulnerable to a rise in sea level and an increase in natural disasters. Hurricanes are expected to become more prevalent and intense in the upcoming decades, while overall annual rainfall is expected to decrease. Average temperatures have already increased more than 1 °C in the past century along with the number of extremely hot days. These trends are anticipated to accelerate by the end of this century.[3]
Rain Pattern	The weather in Dominica is characterized by strong rains, with rainfall ranging from 1,500 mm at sea level to above 6,000 mm in mountainous areas. The island has both a rainy and a dry season, the former between July and December and the latter from January to June. Hurricanes and tropical storms from the Atlantic Ocean occur during the wet season peaking during late August and September.[2,3]
Hydrology	Dominica contains 365 rivers as well as many waterfalls, which are evenly dissipated across the country. The Layou river is the longest and flows from east to west in the central region. The Roseau, Pagua and Toulaman are the other major rivers and flow from the interior down to the coasts. Most streams are non-navigable but can be used for hydropower generation.[2]

ELECTRICITY SECTOR OVERVIEW

At the end of 2020, total installed capacity in Dominica was 26.74 MW that satisfied a peak demand of 15.96 MW. Of the total installed, diesel fuel accounted for 20.10 MW (75 per cent) and hydropower accounted for 6.64 MW (25 per cent) (Figure 1).[4] Minimal solar and wind power also exists within the country but are self-generated at the residential or commercial level.[5] Accurate data on installed capacity of solar and wind power are currently unavailable. There are a total of five major power plants in the country. The two diesel plants are Fond Cole (13.3 MW) and Sugar Loaf (6.8 MW) and the other three are hydropower plants at Laudat (1.24 MW), Trafalgar (3.52 MW) and Padu (1.88 MW). Available capacity in 2020 was lower than installed due to damages to plants, especially at the Padu hydropower plant that has been damaged since Hurricane Maria in 2017 and still has not been repaired.[4,6]

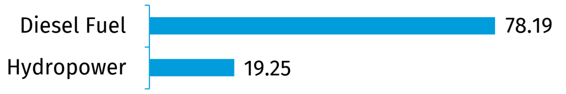
Figure 1. **Installed Electricity Capacity by Source in Dominica in 2020 (MW)**



Source: DOMLEC[4]

In 2020, total electricity generation in Dominica by the country's electricity company, DOMLEC, was 97.45 GWh. Diesel fuel generated 78.19 GWh (approximately 80 per cent) and hydropower 19.25 GWh (20 per cent) (Figure 2). Total electricity sold in the country was 85.5 GWh. Residential customers consumed 40.78 GWh, commercial customers (excluding hotels) consumed 36.41 GWh, industry consumed 3.46 GWh, hotels consumed 2.83 GWh and street lighting consumed 2.03 GWh. Power plants used 3.57 GWh themselves and the remaining 8.37 GWh was considered as losses.[4]

Figure 2. **Annual Electricity Generation by Source in Dominica in 2020 (GWh)**



Source: DOMLEC[4]

Access to electricity in Dominica is 100 per cent.[7] Electricity security in the country, however, is vulnerable to weather volatility and oil price shocks. During the dry season, the hydropower plants are unable to produce at their full capacity.[4] In addition, inclement weather and storms can easily damage the country's electrical infrastructure. Hurricane Maria in 2017 demonstrated how vulnerable the infrastructure was, affecting the entire grid and leaving almost all of the population without power for months. The transmission and distribution system were nearly completely destroyed, with 40 per cent of the system torn down and needing repairs and another 25 per cent was unrepairable and needing to be fully replaced. The irremediable damage was disproportionately higher in rural areas.[5] Since this natural disaster, heavy focus has been put on making the system much more resilient for the future.

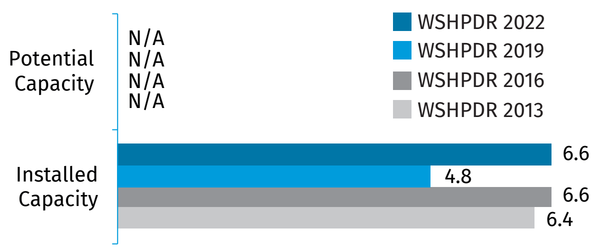
The one electrical utility company in the country is Dominica Electricity Services Limited (DOMLEC). The majority of the company is owned by private investors with Light and Power Holdings being its majority shareholder, owning 52.8 per cent. DOMLEC is the country's principal generator of electricity, although independent power producers (IPPs) are allowed to generate electricity with a licence as per the Electricity Supply Act of 2006. Transmission and distribution rights are still exclusive to DOMLEC. The Independent Regulatory Commission (IRC) is responsible for regulating the sector and issuing the generation licences.[6]

Electricity tariffs in Dominica depend on consumer type. For residential consumers prices are 0.11 USD/kWh for the first 50 kWh and 0.13 USD/kWh for additional consumption above 50 kWh. For industries and hotels prices are 0.12 USD/kWh from 6 am to 10 pm and are 0.11 USD/kWh from 10 pm to 6 am. For commercial consumers and street lighting prices are 0.13 USD/kWh.[8] In April 2022 the IRC was to carry out a tariff review of DOMLEC, with tariff values subject to change as a result.[9]

SMALL HYDROPOWER SECTOR OVERVIEW

The definition of small hydropower (SHP) in Dominica refers to plants of up to 10 MW. The installed capacity of SHP was 6.64 MW at the end of 2020. The country has three SHP plants: Laudat with an installed capacity of 1.24 MW, Trafalgar with 3.52 MW and Padu with 1.88 MW.[4] All three plants are owned and operated by DOMLEC. The exact SHP potential in the country is unknown although it has been found that there is untapped potential within the island. A qualitative hydropower potential assessment indicated there was hydropower potential in the Belfast, Layou, Rosalie, Roseau and White Rivers but the undertaken study did not quantify the potential.[10] In comparison with the *World Hydropower Development Report (WSHPDR) 2019*, potential capacity has remained unknown and installed capacity has recovered its 6.64 MW level due to the knowledge that the Padu plant will not be permanently shut down because of the damage caused by Hurricane Maria (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Dominica (MW)**



Sources: DOMLEC,[4] *WSHPDR 2019*,[10] *WSHPDR 2016*,[11] *WSHPDR 2013*[12]

Hydropower was first implemented in the country in 1952 with the 0.64 MW Old Trafalgar plant and then in 1967 the 1.88 MW Padu plant was commissioned.[13] Decades later, Dominica expanded its electricity generated through hydropower by implementing the Dominica Hydroelectric Expansion Project, which led to the Laudat power plant commencing its service in December 1990. The Old Trafalgar power plant was replaced by the New Trafalgar in September 1991.[14]

In 2017, Hurricane Maria severely affected the entire country, including its existing hydropower facilities. A study of the Roseau River area found that the Trafalgar hydropower plant only experienced minor damages to the building structure, while the Laudat plant remained intact.[15] Conversely, the Padu hydropower plant was severely affected, with the flooding of its powerhouse and damage to its electrical installations. This has caused the plant to be unable to operate, which remained to be so as of the start of 2022. Plans to recover this plant, however, are in place and international bidding for the rehabilitation project was announced in February 2022.[16]

RENEWABLE ENERGY POLICY

A National Energy Policy (NEP) was drafted in 2011 and revised in 2014, asserting the country's objective for self-sufficient electricity generation through sustainable resources by 2020. It suggested that renewable energy should be included in the energy mix whenever economically feasible. Hydropower, solar power and geothermal power were all listed as having high potentials that should be further studied and developed. Geothermal power was the only one quantified with a capacity target, expecting a capacity of 120 MW to be fully operational by 2020.[17] In reality, high set-up costs have severely hindered reaching this expectation so in order to push geothermal development, the Government created the publicly-owned Dominica Geothermal Development Company Ltd. (DGDC) in 2016, which, at the moment of writing of this chapter, was in the process of constructing a 10 MW geothermal project with USD 50 million invested from the Government.[18] This NEP also suggests enacting financial incentives for renewable energy development; however, no such incentives have been put in place.[17]

In response to the immense damage of the electricity infrastructure caused by Hurricane Maria in 2017 and the need for a more resilient system, the Sustainable and Resilient Energy Plan (S-REP) of 2019 was created. This plan stresses the need to strengthen the country's transmission and distribution systems, to diversify the energy mix with more renewable energy sources and to reinforce grid stability for the most vulnerable communities. Analyses of six scenarios of possible energy mixes were carried out to find the most cost-effective way to maximize resiliency and two scenarios were identified as optimal, depending on actual geothermal output achievements. The most optimal scenario constitutes increasing hydropower capacity to 7.2 MW, geothermal power to 12.8 MW and keeping existing diesel for back-up. However, in the case that geothermal power becomes too expensive to implement at such a capacity, then alternatively increasing solar power to 6.2 MW, wind power to 6.6 MW, geothermal power to 6.4 MW and keeping diesel for back-up, would be satisfactory.[19] All sustainable development programmes and projects in Dominica are coordinated by the Environment Coordinating Unit (ECU) of the Ministry of Environment, Natural Resources, Physical Planning and Fisheries. The ECU is funded primarily by internal sources and collaborates with the Government of the Commonwealth of Dominica and the private sector agencies on developing renewable energy policies as well as tackling environmental issues.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The barriers to SHP development in Dominica include:

- The current focus on electricity generated through geothermal resources has shifted the Government interest away from other renewable energy sources;
- Progress in eco-tourism and the frequent use of rivers for this purpose prevents future hydropower development;
- Dominica lacks economic and financial incentive mechanisms for SHP, such as feed-in-tariffs or tax benefits;
- Privately-owned properties make land-acquisition for hydropower difficult.[10]

The enablers for SHP development in Dominica include:

- Hydropower projects have a lower cost of developing than geothermal projects;
- As SHP plants have been in operation in the country for several decades, there is local operating knowledge;
- An increase in hydropower would decrease the country's high dependency on imported fossil fuels.

Dominican Republic

Michela Izzo, Guakía Ambiente; Alberto Sánchez, GEF Small Grants Programme; and Mario Vera Barranco, Guakía Ambiente

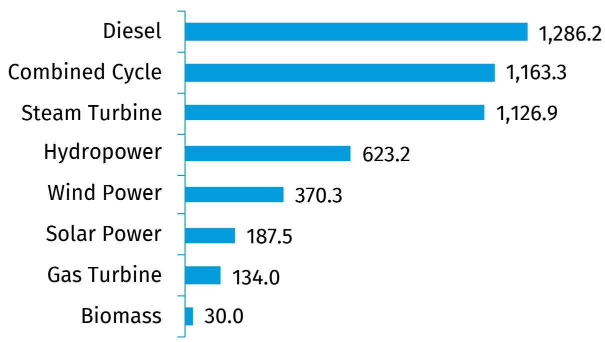
KEY FACTS

Population	10,448,499 (2020) [1]
Area	48,311 km² [2]
Topography	The Dominican Republic has four main mountainous chains: the Cordillera Septentrional, the Cordillera Central, the Sierra de Neyba and the Sierra de Bahoruco. These chains run approximately parallel to each other with a north-west, south-east orientation and are separated by three major valleys: the Cibao, the San Juan and the Enriquillo. Pico Duarte is the highest peak in the country, on the island of Hispaniola and in the entire Caribbean, reaching 3,098 metres.[3]
Climate	The Dominican Republic has a tropical climate, ranging from arid to very humid, with high ecosystem diversity. This is associated with the physical geography of the country that is characterized by mountain chains, which create a barrier to trade winds, producing very different conditions between the windward and leeward sides. The average temperature ranges between 7 °C (at the highest altitudes) and 31 °C (at the Enriquillo Lake in the southern region).[3]
Climate Change	Historical trends show a significant increase in air temperature (3.0±0.5 °C for minimum and 1.8±0.4 °C for maximum air temperature in the period 1936–2007) and significant change in rain patterns, with typical reduction in precipitation on the leeward side of the main mountain chains and the western side of the country.[4] These trends are expected to continue and intensify in the future, according to the most accredited climate change scenarios.[5]
Rain Pattern	Variations in topography lead to differences in precipitation of up to 2,400 mm between the north-eastern and south-western sides of the Cordillera Central. The wettest areas are located in the north-eastern part of the country, which receive annual rainfalls of over 3,000 mm, while the driest areas can be found in the Enriquillo Valley, in the south-west, with less than 450 mm of precipitation per year.[3]
Hydrology	The Yaque del Norte (296 km) is the longest river in the Dominican Republic. The longest river on the island of Hispaniola is the Artibonite (321 km); however, only 68 km of it are located in the Dominican Republic. On the other hand, the largest river of the country is the Yuna, with an average flow of 97.6 m³/s.[6] Lake Enriquillo is the largest lake not only in the Dominican Republic, but also in the entire West Indies.[3]

ELECTRICITY SECTOR OVERVIEW

In 2020, total installed capacity in the Dominican Republic stood at 4,921.4 MW, representing an increase of approximately 42 per cent compared with 2016. Of the total installed capacity, approximately 26 per cent came from diesel plants, 24 per cent from combined cycle plants, 24 per cent from steam turbine plants and 3 per cent from gas turbine plants (Figure 1). Renewable energy sources contributed approximately 24 per cent of the total, with hydropower, the country's most important energy source after fossil fuels, providing 13 per cent and wind power plants 8 per cent. Biomass was recently added to the country's energy mix, with a 30 MW plant installed in the south-east of the country.[7,8,9]

Figure 1. **Installed Electricity Capacity by source in the Dominican Republic in 2020 (MW)**



Source: OCSENI,[7] Sanchez & Izzo[9]

Total gross generation in 2020 reached 18,687.6 GWh, while net supplied electricity was 17,411.5 GWh. Of total electricity generation, coal contributed 35 per cent (with a significant increase from previous years due to the launch of the Punta Catalina power plant), natural gas 33 per cent, fuel oil 17 per cent, hydropower 7 per cent, wind power 6 per cent, solar power 2 per cent and biomass 1 per cent (Figure 2). Relative to the *World Small Hydropower Development Report (WSHPDR) 2019*, there was a significant increase in both generation from fossil fuels (especially carbon and diesel) and generation from renewable energy sources, especially solar and wind power, while generation from hydropower remained basically stable.[7,8,9]

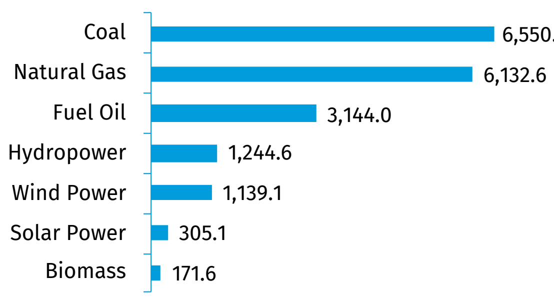
Figure 2. **Electricity Generation by Source in Dominican Republic in 2020 (GWh)**

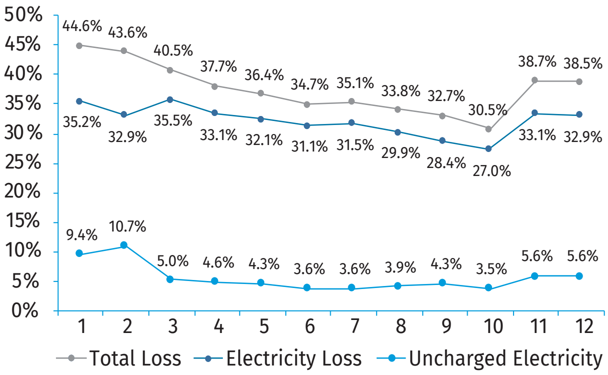


Source: OCSENI,[7] Sanchez & Izzo[9]

The national electricity system of the Dominican Republic has progressively improved in quality. Nevertheless, problems persist, both in terms of energy provision and in terms of quality of transmission and distribution. In order to limit losses and reduce the electricity subsidy, the distribution enterprises (EDEs) have established maximum unit costs for dispatch to the National Interconnected Electric System (SENI), consequently causing an unsatisfied demand. In 2020, the monthly average power demand supply shortfall was 60 MW.[7] Furthermore, the electricity system is characterized by frequent interruptions and a high loss rate both in the transmission and distribution system — over 30 per cent of the total generated electricity (Figure 3).[10] The Dominican Republic experiences one of the highest frequencies of blackouts among countries in the region, exceeding 30 days annually on average.[11] Available capacity stands on average at approximately 22 per cent of installed capacity.[12]

The inability to provide a reliable service at reasonable prices has caused a segmentation of the electrical market into three main groups: SENI's users, who are connected to the national grid and constitute 83 per cent of the market at present; self-producers (10 per cent of the market), typically large consumers such as industrial and mining companies that have their own generation systems to satisfy their internal demand and sell the surplus to SENI; and isolated systems (7 per cent of the market), which operate independently and are not connected to SENI.[13]

Figure 3. **Electricity Loss Rate of Distribution Enterprises as a Percentage of Electricity Charged in the Dominican Republic in 2009–2020 (%)**

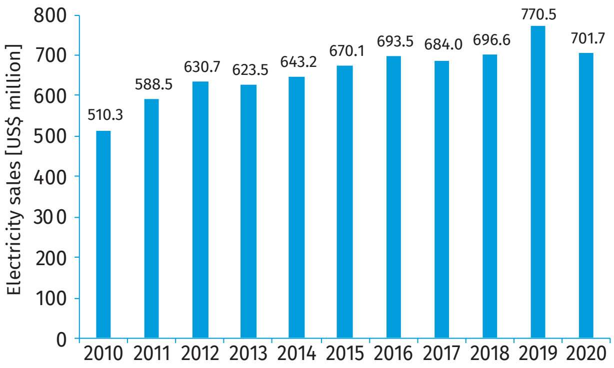


Source: CREES[10]

In terms of access to electricity, the Dominican Republic has made progress in recent years, reaching 100 per cent of urban electrification, while in rural areas electricity access is estimated at 98 per cent.[14,15]

Fossil fuels, which are imported, continue to be the main source of fuel for electrical generation. Given the rising trend in electricity demand, the rate of fossil fuel consumption related to electrical generation is also growing. The expenditure of the residential and commercial sectors on electricity has increased by more than 40 per cent between 2009 and 2019 (Figure 4).[7,16] National projections indicate that energy demand will continue to grow at an average rate of 2–3 per cent per year in the period 2010–2030.[17]

Figure 4. **Electricity Sales to Regular Commercial and Residential Customers in the Dominican Republic in 2009–2019 (USD million)**



Source: CDEEE[16]

The Dominican electrical system is state-owned. However, both the Government and the private sector participate in the generation, transmission, distribution and commercialization of energy. The Coordinator of the National Interconnected System (OCSENI) is the state agency responsible for coordinating the transmission, generation and distribution within SENI. Through Law 141–97, five enterprises were created, two for thermal generation (Electricity Generation Enterprises ITABO and HAINA — EGEITABO and EGEHAINA, respectively) and three for distribution (Electricity Distribution Enterprises of the North, South and East — EDENORTE, EDESUR and EDEESTE, respectively). Both transmission and hydropower generation belong to the state, through two enterprises: one for transmission (Dominican State Transmission Enterprise — ETED) and one for hydropower (Dominican Hydropower Generation Enterprise — EGEHID). The Dominican Corporation of State Electrical Enterprises (CDEEE) is responsible for the management of electrical enterprises and the implementation of state programmes for rural and urban electrification, guaranteeing synergy, effectiveness, profitability and sustainability.[8]

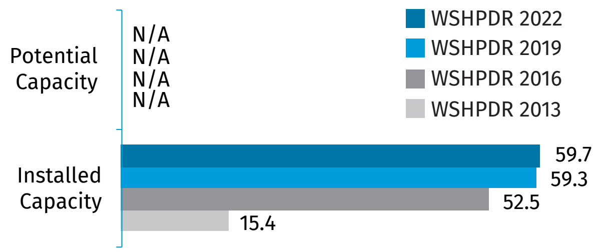
The Dominican Republic continues to have one of the most expensive electrical systems in the Caribbean and Central America. In 2019, final customers had to pay more than 0.15 USD/kWh, over two times the 0.06 USD/kWh paid by customers connected to the off-grid community-owned hydropower plants supported by the Small Grants Programme and the Government of the Dominican Republic, as outlined below.[9,16,18]

There are two different types of electricity subsidies in the Dominican Republic. The first type is the "Bonoluz, 3 in 1", which is a full subsidy of electricity consumption up to 100 kWh for customers who have been selected by the Social Cabinet of the Government. For additional consumption, a further subsidy is provided in the form of a lower tariff, and the fixed charge for consumption is also fully subsidized. The second type of subsidy is the Fund for the Stabilization of the Electric Tariff (FETE) which compensates tariff differences caused by the fluctuations in the cost of imported fuels used for power generation.[8]

SMALL HYDROPOWER SECTOR OVERVIEW

In the Dominican Republic, small hydropower (SHP) is classified as plants with a total capacity of up to 10 MW. Installed SHP capacity in 2020 stood at approximately 59.7 MW, with a total of 76 operational SHP plants, which contributed nearly 10 per cent of the total hydropower installed capacity.[9,19] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed capacity slightly increased due to the construction of additional community-operated SHP plants, while the nationwide potential remains unknown (Figure 5).

Figure 5. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in the Dominican Republic (MW)**



Source: Sánchez & Izzo,[9] *WSHPDR* 2019,[8] EGEHYD,[19] *WSHPDR 2013*,[20] *WSHPDR 2016*[21]

In 2020, there were 16 state-owned SHP plants consisting of 22 individual power blocks operating in the country with a combined installed capacity of 57.8 MW, all operated by EGEHID.[7] More than 60 per cent of the plants have a capacity of less than 2.5 MW. The majority of these SHP plants, accounting for 80 per cent of the total SHP installed capacity, are located in the Cordillera Central, the main mountain chain of the country. The real capacity of the state-owned SHP plants available to the national electricity system of the Dominican Republic is approximately 45 per cent of their installed capacity on average. In addition, as of 2020 there were 56 community-owned micro-hydropower plants operating in the country, of which 47 were constructed through a partnership between the Government of the Dominican Republic and the Global Environment Facility Small Grants Programme (GEF SGP) and a further 9 were financed solely by the Government. The capacities of these micro-hydropower plants range from 10 kW to 150 kW, with a combined installed capacity of 1.5 MW (Table 1).[7,30]

A comprehensive study on SHP potential in the Dominican Republic has not yet been carried out. One study, which was due to start in 2018 as a collaboration among the Ministry of Energy and Mines, the GEF SGP, the Technological Institute of Santo Domingo (INTEC) and the Dominican non-governmental organization Guakía Ambiente, was delayed. Nevertheless, a pilot study to evaluate micro-hydropower potential was carried out as part of an MSc thesis in 2020, as a collaboration between the University of Madrid, Guakía Ambiente and the GEF SGP. The pilot study was implemented in the Nizao basin, a 1,038 km^2 watershed in the south-eastern region and one of the priority basins of the country, both in terms of water provision and of electricity generation.[25] The study identified 72 river sections appropriate for the installation of micro-hydropower plants: 27 sections between 19 kW and 40 kW, 19 between 40 kW and 70 kW, 13 between 70 kW and 148 kW, 4 between 148 kW and 244 kW, 5 between 244 kW and 372 kW and 4 of more than 372 kW.[26] While these partial results cannot be adopted as an estimate of the nationwide SHP potential, the results and their potential applications confirm the importance of expanding the pilot study to the whole country.

The aforementioned study is especially relevant to organizing rural electrification in a more efficient and effective way, due to the significance that community micro-hydropower generation has acquired in the Dominican Republic as a successful model for sustainable development. The Dominican Government, following Law 57-07 on Incentives to Renewable Energy and in collaboration with multiple stakeholders, continues to promote micro-hydropower as a solution to guarantee electricity access to rural communities while fostering local empowerment. As of 2021, 60 community-owned micro-hydropower plants were in operation, providing clean reliable energy to more than 4,600 families, schools, rural health and community centres, micro-enterprises and communication centres in rural isolated areas. Furthermore, these systems are contributing to global warming mitigation, with a reduction of more than 28,000 tons of CO_2 per year and conservation of over 70 km^2 of forest.[9,27,28,29]

Ten additional SHP plants are currently under construction, with a total capacity of more than 490 kW, which will benefit over 1,100 additional families in isolated rural areas.[27] Several ongoing projects are listed in Table 2, while one potential identified SHP site is listed in Table 3.

Due to the COVID-19 pandemic, community micro-hydropower projects in the Dominican Republic have suffered delays and difficulties, which have slowed the increase in the number of such plants throughout the country.

The Dominican Republic is sharing its successful experience in community micro-hydropower with other Latin American countries (Venezuela, Haiti and Mexico), promoting the application of principles that ensure a sustainable model of micro-hydropower development:

- Community-based approach;
- Development of local solutions;
- Replicability, through adaptation to each specific context;
- Local empowerment, based on the following: respect for the habits and peculiarities of local populations; active participation of people and local groups; learning by doing; improvement of local skills and knowledge; integrated development; and networking and multi-stakeholder synergy. [31]

RENEWABLE ENERGY POLICY

One of the instruments of national policy on renewable energy in the Dominican Republic is the Incentive to the Development of Renewable Energy Sources (Law 57-07) and the corresponding regulations (in particular, No. 10469 of 30 May 2008). The law introduced a target of 20 per cent of national energy consumption to be produced from renewable energy sources by 2020, with the aim of reducing the dependence on imported oil and other liquid fuels. This goal is confirmed by the National Strategy of Development 2030 (Law 01-12), which set the goal of reducing per capita CO_2 emissions by 25 per cent by 2030 with respect to the 2010 baseline.[32] The Government will continue promoting renewable energy over the coming decade, planning to generate 23 per cent of all electricity at the national level from renewable energy sources by 2030. These goals will be reached through structural interventions to improve the national electricity system, as well as changes to the national energy mix.[10]

The regulations for the application of Law 57-07 establish incentives and feed-in tariffs (FITs) for renewable energy, according to the specific source. However, these do not apply to hydropower, small or otherwise. For other RES, FITs range from 0.0487-0.5350 USD/kWh.[29]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

SHP projects are primarily regulated by the General Law on Electricity (125-01), which created the Dominican Hydropower Generation Enterprise (EGEHID), the entity that is responsible for managing all hydropower owned by the Government of the Dominican Republic.[33] SHP projects up to 5 MW can apply for incentives under Law 57-07. In these cases, the state grants concessions to private companies or individuals.

COST OF SMALL HYDROPOWER DEVELOPMENT

Cost of SHP development is highly variable, depending on site conditions, accessibility, technology and grid distribution (where applicable). At present, no case studies are available on the matter. According to the experience of the GEF SGP, the cost of SHP development in the Dominican Republic falls within the range of 6,500–19,500 USD/kW.[34]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

A variety of financial mechanisms are implemented for project development. In case of the Government-developed projects, most have been financed by loans from international banks and less frequently through local funds by selling energy through EGEHID. In case of community SHP projects, financial mechanisms are based on different sources, including international cooperation, the national Government, the private sector, civil society organizations and local communities. During the past 20 years, the GEF SGP has been the main promoter of SHP, with the implementation of more than 50 projects.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Climate crisis is significantly affecting SHP development in the Dominican Republic. On the one hand, the increase in frequency of intense rain, as well as in intensity of tropical cyclones, exposes SHP infrastructure to damage, causing suspension of operations.[4,35] On the other hand, prolonged and intense droughts significantly reduce water flow, thus causing shortages in the provision of electricity.[32] A recent study, carried out on SHP projects supported by the GEF SGP and Guakía Ambiente, revealed that during the period 2015–2018, characterized by the incidence of El Niño, approximately 30 per cent of the plants reduced their generation, while another 15 per cent went out of operation for at least one month.[36]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

SHP generation continues to be a feasible alternative to fossil fuels for electrification in the Dominican Republic, especially in rural isolated areas, where a small percentage of the population persists without access to electricity. Decentralized management is highly recommended to ensure sustainability and to promote local development, especially in case of SHP plants with an installed capacity up to 500 kW.

Many barriers to effective SHP development in the country persist and additional challenges have arisen in recent years, including the following:

- Climate change impacts including intense rain, tropical cyclones, and prolonged drought;
- Insufficient data on undeveloped SHP capacity and potential sites, particularly on the national level;
- Lack of private sector engagement in SHP development;
- Lack of opportunities and mechanisms for knowledge exchange in the SHP sector;
- Lengthy administrative procedures, especially for community-run SHP projects.

Enablers for SHP development include:

- Experience with SHP development and operation and well-organized SHP sector;
- Availability of international financing for SHP projects;
- Some studies of potential SHP sites are available.

Recommended measures in support of SHP development in the Dominican Republic include the following:

- Carrying out a study on SHP potential at the national level;
- Decentralization in decision making;
- Diffusion of a shared vision of integral development, based on local empowerment as a key assumption for sustainability;
- Capacity building for fund management at community level;
- Strengthening of public-private-community alliances, through effective mechanisms of collaboration towards common objectives;
- Opening of opportunities for feeding directly into the grid for SHP plants up to 5 MW;
- Effective application of Law 57-07, especially regarding the commitment to devote 5 per cent from taxes on fossil fuels to renewable energy;
- Providing access to Bonoluz subsidy for households connected to micro-hydropower plants;
- Easy access to the carbon market for community micro-hydropower projects;
- Networking to facilitate knowledge exchange and promote mutual support, while focusing on tackling existing issues in the energy sector;
- Climate change adaptation and land degradation reduction in the main watersheds of the country;
- Ensuring reliable data availability and access.

Grenada

Laura Stamm, International Center on Small Hydro Power (ICSHP)

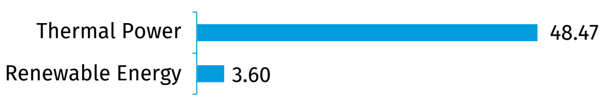
KEY FACTS

Population	112,519 (2020)[1]
Area	345 km² (incl. the islands of Grenada, Carriacou and Petite Martinique)[2]
Topography	The oval-shaped main island of Grenada has a rugged terrain of volcanic origin. It features several forested steep slopes rising from sea level. The highest point is Mount Saint Catherine at 840 metres, situated towards the northern interior of the island.[2]
Climate	Grenada has a tropical climate, with an average temperature of 28 °C. Daytime temperatures vary between 26 °C and 32 °C, while at night temperatures can drop to between 19 °C and 24 °C. There is little variation in temperature throughout the year and seasons are categorized by precipitation with the dry season being between January and May and the wet season between June and December.[3]
Climate Change	An increase in major natural disasters is the most critical concern for Grenada on the issue of climate change. Hurricanes are expected to become larger and more frequent in the upcoming decades. In addition, a rise in sea levels could cause devastating damage to the country as most of the population and infrastructure is located along the low-lying coasts. Sea levels have started to rise on the shores at an average rate of 3.6 mm per year since 1993. Some rivers, already prone to flooding, will also most likely experience more dramatic floods in the future.[4]
Rain Pattern	Rainfall varies between altitudes and seasons. Average precipitation on the coasts is 1,500 mm per year and can reach approximately 4,000 mm per year in the interior highlands. The most rainfall is experienced between June and December. It is during these months that tropical storms or hurricanes can occur.[2]
Hydrology	The country has over 70 rivers, mostly small, typically flowing downwards from the higher altitudes in the interior. Of these, there are eight rivers of consequence: Grand River, Beausejour, Pearls, Saint Patricks, Bailes Bacolet, Antoine, Saint Johns and Saint Marks. The rivers are subject to flooding during the wet season, particularly in the upper parts in higher elevations. The largest lake is Grand Etang with a surface area of 8 hectares, located in a dormant volcanic crater.[3]

ELECTRICITY SECTOR OVERVIEW

At the end of 2020, the total installed capacity in Grenada was 52.07 MW that satisfied a peak demand of approximately 32 MW. Over 93 per cent, more than 48 MW, of the capacity was thermal power, primarily diesel fuel. The remaining 7 per cent, or almost 4 MW, was from renewable energy sources, primarily solar power and minimal wind power (Figure 1). The majority of the renewable energy (2.4 MW) was generated through solar photovoltaics (PV) panels of private customers whose excess after personal use is fed back into the grid.[5]

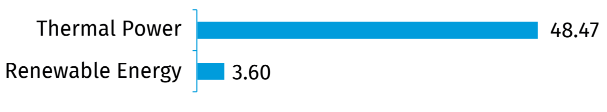
Figure 1. **Installed Electricity Capacity by Source in Grenada in 2020 (MW)**



Source: GRENLEC[5]

Total electricity generation in Grenada for the year of 2020 was 222.7 GWh. Thermal power generated 218.5 GWh, or 98 per cent, and the remaining 4.2 GWh, or 2 per cent, was generated with renewable energy (Figure 2). Subtracting the energy used to operate the power plants themselves, total net electricity generation was almost 213 GWh. Of this, just under 105 GWh (49 per cent) was consumed by the commercial sector, 84 GWh (39 per cent) was consumed by the residential sector and 11 GWh (5 per cent) was used for street lighting. The country experienced an approximately 7 per cent loss in electricity for the year.[5] The electrification rate in Grenada was over 95 per cent as of 2020.[6]

Figure 2. **Annual Electricity Generation by Source in Grenada in 2020 (GWh)**



Source: GRENLEC[5]

Grenada Electricity Services Limited (GRENLEC) is the only electricity company in the country and is therefore responsible for all the generation, transmission and distribution of electricity. GRENLEC was a state-owned company prior to 1994 when it was privatized due to the passing of the Electricity Supply Act that year. The act guaranteed GRENLEC as the sole producer of electricity in the country, but allowed ownership of the company to be transferred to private entities. Consequently, controlling shares were sold to WRB Enterprise from the United States.[7]

The sector was then restructured with the passing of the new Electricity Supply Act of 2016 and the Public Utilities Regulatory Commission Act of 2016. These acts ended GRENLEC's monopoly in the sector, allowing for new entities, domestic or foreign, to begin generating electricity including self-generation for individuals and created a regulatory commission to oversee tariffs in the sector.[7,8] The Electricity Supply Act also called for the promotion of renewable energy and obligates preference given to generators of renewable energy for licences.[9] In the years following the acts, GRENLEC remains the principal supplier of electricity, although its ownership has changed. As of December of 2020, the Government of Grenada repurchased over 71 per cent of the company's shares from WRB Enterprises, making the state the majority owner again.[5]

The base rates of electricity in Grenada depend on the type of consumer in which some types also carry a surcharge for horsepower, floor area or an environmental levy. A value-added tax (VAT) is then added to the final cost for all consumers. Fuel surcharges are calculated based on a three-month average. In March 2022, the base fuel charge for all types of consumers was XCD 0.5288 (USD 0.20) per kWh. The non-fuel charge is different for each type of consumer: for domestic customers it is XCD 0.3043 (USD 0.11) per kWh, for commercial customers it is XCD 0.3281 (USD 0.12) per kWh, for industrial customers it is XCD 0.2405 (USD 0.089) per kWh and for street lighting it is XCD 0.2875 (USD 0.11) per kWh.[10]

SMALL HYDROPOWER SECTOR OVERVIEW

As there is no local definition for small hydropower (SHP). In this chapter it is defined as plants with a capacity of up to 10 MW. While potential SHP capacity in Grenada is estimated to be approximately 7 MW, there is currently no installed capacity. This information remains the same compared to the previous editions of the *World Small Hydropower Development Reports (WSHPDR)* (Figure 3).

In the past, sugar cane estates used hydro wheels to operate mills, but none of these early hydropower plants are in operation today. Several studies have been undertaken to assess the hydropower potential in the country. An analysis carried out in 1981 by the French firm SCET concluded that Grenada has a cumulative potential of at least 7 MW. In 1984, six potential hydropower projects were analysed in a pre-feasibility study at the Great, Marquis and St. Mark's Rivers. In 1991, the British consulting firm MRM Partnership confirmed the hydropower potential of the Great River Upper Basin, including a 720 kW Birchgrove and a 380 kW Belvidere hydropower projects.[11] In 2018, a grant of approximately USD 100,000, most of which financed by the Global Environment Facility (GEF), was approved for a 30 kW hydropower project in Birchgrove, however completion of the construction has not been announced as of yet.[14] Additionally, in 2022, the German Development Corporation (GIZ) was partnering with the Government of Grenada and its water authority, the National Water and Sewage Authority (NAWASA), to bring the possibility of pumps-as-turbines technology to the island, which, if implemented, will generate hydropower in existing water pipes that currently bring potable water from the mountains down to the coasts.[15]

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Grenada (in MW)**

Source: *WSHPDR 2019*,[11] *WSHPDR 2016*,[12] *WSHPDR 2013*[13]

SHP development in Grenada has not been explicitly prioritized by the Government further than the general goal to expand renewable energy declared in the Energy Supply Act of 2016. The National Energy Policy of 2011 specifically discusses solar power, wind power and geothermal energy but does not mention hydropower.[16] Nevertheless, any SHP generation development would be granted grid preference under the Energy Supply Act and would be regulated as per the Public Utilities Regulatory Commission Act. Financing for these projects would most likely come from international donors, such as foreign organizations or development banks.[11]

RENEWABLE ENERGY POLICY

The National Energy Policy of 2011 states the importance of transitioning to renewable energy and set the goal to generate 20 per cent of the country's energy from renewable sources by 2020.[16] This goal was made with the idea that geothermal energy would be in operation by then, however, it has still not yet been developed and therefore the goal was not reached. Additionally, in the country's first Nationally Determined Contribution of 2016, a target was set to reach an installed capacity of 15 MW of geothermal energy, 10 MW of solar energy and 2 MW of wind energy by 2025, but the second Nationally Determined Contribution of 2020 recognized that this target will most likely not be met.[17,18]

The national power company, GRENLEC, offers a Renewable Energy Interconnection Programme that allows private owners of solar PV systems to sell the extra energy produced back into the grid. This is a net-billing system where customers receive credit for the value of the amount of fuel that was avoided due to the solar power supplied.[19] Owners of the renewable energy-based generators selling electricity to GRENLEC are remunerated either at a fixed rate of XCD 0.45 (USD 0.17) per kWh or at a variable rate equal to the average fuel price per kWh of the previous year, which for 2022 was XCD 0.37 (USD 0.14) per kWh.[10] As of 2020, over 2.4 MW was connected to the grid from customers in this programme.[5]

BARRIERS AND ENABLERS FOR SMALL HYDRPOWER DEVELOPMENT

The key barriers to SHP development in Grenada include:

- The national focus being on geothermal and solar power resources, with a secondary focus on wind power, while hydropower does not play any role in the country's energy supply planning;
- No incentives or other special framework conditions for hydropower development have been created;
- The country's hydropower potential is poorly investigated;
- The lack of local expertise in hydropower.

The key enabler to SHP development in Grenada is as follows:

- With high dependency on diesel fuel and unmet goals to reach a level of 20 per cent of energy sourced from renewable energy, hydropower can be used to help reach the country's goal.

Guadeloupe

Oluwatimilehin Paul Olawale-Johnson, International Center on Small Hydro Power (ICSHP)

KEY FACTS

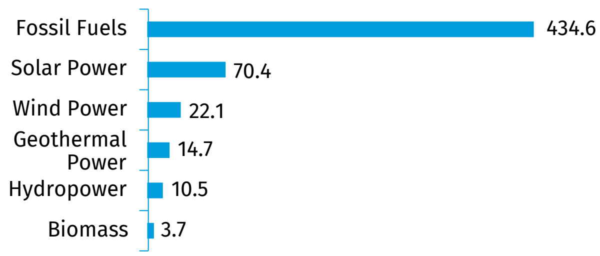
Population	400,020 (2021) [1]
Area	1,690 km^2 [1]
Topography	Composed of the two main islands of Basse-Terre and Grande-Terre, Guadeloupe is an archipelago that also includes multiple smaller islands. The two main islands are joined together only by a few bridges on a narrow sea channel and a mangrove swamp. Guadeloupe is characterized by a volcanic relief, with its highest point measuring 1,467 metres on the Soufriere Volcano.[2]
Climate	The climate is tropical, characterized by humidity and high temperatures all year round. A remarkable stability is observed in monthly temperatures, which may be attributed to *Les Alizés*, the trade winds. There are two main and distinct seasons in Guadeloupe: the rainy season lasting between June and November and the dry season commencing in December and ending in May. Average temperatures in inland and coastal areas differ by only a few degrees Celsius. In inland areas, temperatures are between 19 °C and 27 °C, while on the coast temperatures reach 22–30 °C. The region is affected by hurricanes that most frequently occur in September, but also anytime during the rainy season, between June and November.[3]
Climate Change	With climate change and the progressive sea level rise, the archipelago is highly exposed to coastal risks, particularly given the increasing concentration of population and economic activities along the coast.[4] Climate change is predicted to lead to the deterioration of coastal areas, erosion of beaches and coral beds, increasing likelihood of flooding and water stagnation in coastal plains, which will eventually damage the soil resistance and coastal infrastructures such as sanitation, drinking water, electricity and roads. Average temperatures are expected to increase by 1.6–4.3 °C by 2010 and heavy rains are expected to become 5–10 times more frequent.[5]
Rain Pattern	The average annual precipitation is 1,814 mm. Rainstorms pass very quickly in general and rain showers are likely to occur at any time during the year, not only between June and November. September is considered the wettest month, while February is historically the driest.[6]
Hydrology	The Guadeloupe National Park on the island of Basse-Terre, where most rivers are located, is the main source of water in Guadeloupe.[5] Some of the most important rivers in Basse-Terre are the Lézarde, Moustique, Rose and Petite Rivière à Goyaves. Canal Perrin and Rivière des Coudes are located on Grande-Terre. Grande-Terre and Basse-Terre are separated by the Salt River. Small islands and the dry regions of Grande-Terre are supplied with water through the developed storage capacities and tapped resources.[7,8]

ELECTRICITY SECTOR OVERVIEW

In 2020, the total electricity generation in Guadeloupe was 1,689 GWh.[9] Most of the electricity was generated from fossil fuels such as diesel and coal. Only approximately 23 per cent was from renewable energy sources (Figure 1).

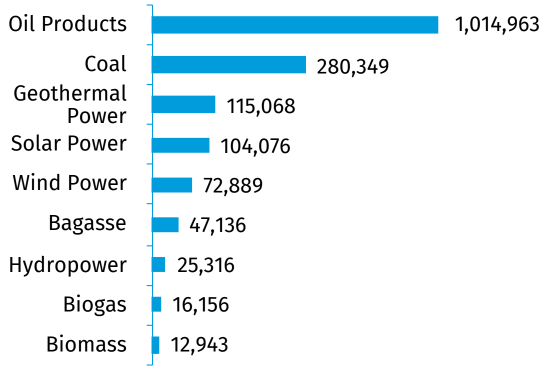
The total installed electricity capacity in Guadeloupe was 556 MW in 2018, with 435 MW from fossil fuel-fired plants and 121 MW from renewable energy sources (Figure 2).[10] Guadeloupe is, thus, highly dependent on fossil fuel generation (coal, diesel and combustion turbines), which account for 80 per cent of the electricity consumed in the archipelago.[11]

Figure 1. **Annual Electricity Generation by Source in Guadeloupe in 2020 (MWh)**



Source: DEAL[9]

Figure 2. **Installed Electricity Capacity by Source in Guadeloupe in 2018 (MW)**



Source: NREL[10]

The Guadeloupe Archipelago is a non-interconnected zone and generates all of its electricity. The islands are connected via submarine cables linked to the network of overhead lines covering Basse-Terre and Grande-Terre.[11]

The Electricity of France (EDF) is the transmission and distribution utility on the archipelago and also operates a significant portion of the country's fossil energy generation. There are also some independent power producers (IPPs), which primarily produce renewable electricity. The Commission for Regulation of Energy (CRE) regulates the electricity sector in Guadeloupe.[12]

Electricity tariff rates in Guadeloupe are defined by the French electricity regulations and are approximately USD 0.19 per kWh.[10,13]

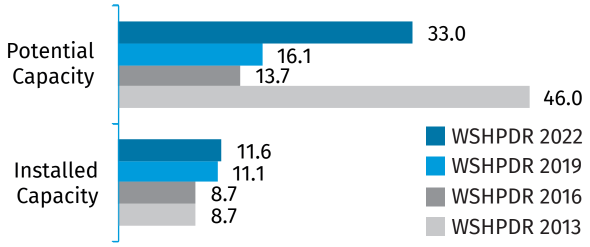
SMALL HYDROPOWER SECTOR OVERVIEW

Small hydropower (SHP) is defined in Guadeloupe as hydropower plants with capacity up to 10 MW. According to the Department of Environment, Planning and Housing (DEAL), Guadeloupe has 16 SHP plants with a total installed capacity of 11.59 MW (Table 1).[14] The existing plants are mainly located in Basse-Terre, due to the combination of available water conditions and suitable topography. These plants are primarily integrated into four irrigation networks and are spread over the Capesterre Belle Eau, Baillif and Vieux-Habitants Rivers. The only plants on Grande-Terre are the Letaye and Gaschet SHP plants.[15]

In 2019 and 2020 SHP plants produced 44 GWh and 25 GWh of electricity, respectively, representing approximately between 2 per cent and 3 per cent of the electricity consumed in the country.[14] The drastic decrease in SHP generation between 2019 and 2020 was due to a 30–40 per cent lower than average precipitation in 2020, which led to the prioritization of other water uses over electricity generation.[16]

Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, the SHP installed capacity slightly increased due to access to more accurate data (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Guadeloupe (MW)**



Sources: DEAL,[14] Region Guadeloupe,[15] *WSHPDR 2013*,[17] *WSHPDR 2016*,[18] *WSHPDR 2019*[19]

The SHP potential is estimated to be 33 MW for an average annual generation of 98 GWh. This potential is concentrated in Basse-Terre, with the development potential being limited by the boundaries of the Guadeloupe National Park. The national park stretches across most of Basse-Terre, therefore, power plants may only be sited on its perimeter. Overall, the development of hydropower in Guadeloupe is constrained by many factors, including energy regulations, in particular, environmental regulations, as well as by the high costs associated with land clearing and connection to the grid. Taking these factors into account, it is estimated that only 25 MW of hydropower capacity can be developed under ideal conditions, for a possible annual generation of 75 GWh.[15,20]

Table 1. **List of Installed Small Hydropower Plants in Guadeloupe**

Name	Installed capacity (MW)	Operator	Launch year
La Rose	2.50	VALOREM	2016
Bovis	0.20	VALOREM	2008

RN2	0.20	VALOREM	–
Dongo	0.07	VALOREM	–

Source: DEAL,[14] VALEMO,[21] Region Guadeloupe[22]

Most SHP plants in Guadeloupe are operated by VALOREM, a renewable energy operator that entered the country's market in 2018. Initially the company was involved in the wind power sector, but in 2019 expanded into hydropower by acquiring 14 SHP plants from Force Hydraulique Antillaise SAS (FHA).[21]

RENEWABLE ENERGY POLICY

In recent years, Guadeloupe has adopted measures for the development of renewable energy sources. As of 2021, its electricity mix consisted of 23 per cent of renewable energy.[8] A range of projects have been developed to size and install renewable power plants in the country.[10] In 2017, the 2016–2023 Multi-Year Energy Programme (PPE) was approved, replacing the Regional Plan for Renewable Energy and the Rational Use of Energy (PRERURE). The PPE aims to reduce final energy consumption by 10 per cent by 2023 and limit the increase in electricity consumption demand to +4 per cent in the same year. It also highlights the objective to achieve a 50 per cent share of renewable energy in final energy consumption, develop 261 MW of additional renewable energy capacity by 2023 (relative to 2015) and achieve energy independence by 2030.[23]

The current technology and the regulatory environment limit the future expansion and upgrades of existing hydropower facilities. While the PPE encourages proposals for enhancing existing production capacities or developing new ones, the PPE is more aimed at strengthening systems to manage energy demand and developing other renewable energy sources, whereas for hydropower no new developments are planned.[17,23]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The main barriers to further development of SHP in Guadeloupe are the following:

- Environmental standards are strict and the construction of new SHP plants may be slow to ensure compliance;
- Significant water resources for micro-and small-scale hydropower are located in the National Park, which is a protected area;
- High costs for grid connection and area clearing;
- There is more interest in the development of other renewable energy sources, rather than SHP, as after multiple feasibility studies, it was concluded that solar, geothermal and wind power are the most cost-effective alternatives.

The enabling factors for SHP development in Guadeloupe include:

- The hydropower sector development, including optimization of existing capacities, is actively encouraged in the PPE;
- Guadeloupe has IPP experience in renewable energy project development.

Haiti

Pierre Kenol Thys, Inter-American Development Bank; and Laura Stamm, International Center on Small Hydro Power (ICSHP)

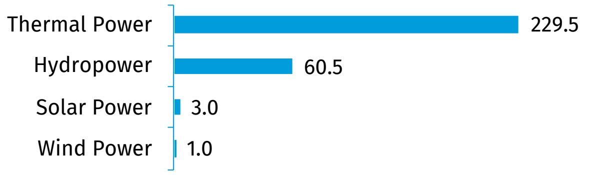
KEY FACTS

Population	11,402,533 (2020)[1]
Area	27,750 km^2 [2]
Topography	The terrain is predominantly rugged with approximately two-thirds of the territory lying at elevations above 490 metres. The coastline is largely irregular with rocky shores and cliffs. The major mountain ranges run in an east-west orientation such as the Northern Massif, the Matheux Mountains that extends into the Trou d'Eau Mountains on its eastern end, and the Massif de la Hotte that extends into the eastern Massif de la Selle. The country's highest peak, Mount La Selle, reaches 2,674 metres and is located in the south-eastern Massif de la Selle. Two minor ranges, the Cahos and Noires Mountains are located in the central region and surround the Central Plateau, a flat region with an average elevation of 300 metres. With a long fault line crossing the southern part of the country and passing just south of the capital city Port-au-Prince, the country is subject to periodic seismic activity.[2]
Climate	Haiti generally has a tropical climate. Average temperatures vary greater between altitudes than throughout the year. Near sea level, temperatures range from 25 °C in January and February to 34–36 °C in July and August. In higher elevations, temperatures average 16 °C and frost can occur during the winter months. [2]
Climate Change	As an island state in the Caribbean, the country's largest climate risks are the rising of sea levels and surges in natural disasters. In the upcoming decades, an increase in the prevalence and intensity of hurricanes and tropical storms is anticipated. At the same time, overall rainfall is expected to decrease, as it already has been decreasing at a rate of 5 mm per month per decade since 1960. Additional concerns are that the tendencies of coastal erosion, landslides and droughts will most likely intensify.[3,4]
Rain Pattern	Annual rainfall varies between regions and elevation. The northern and eastern mountainous regions experience the most rainfall with an average of 1,200 mm per year. Western regions with low elevations and La Gonâve Island receive closer to 550 mm per year. Generally, the wet season is between May and November, but some regions experience a minor dry season between June and August.[4]
Hydrology	The Artibonite is the longest river on the island at 280 kilometres. It begins in the Northern Massif (the Cordillera Central) in the western Dominican Republic and flows south-westwards along the border with Haiti, draining into the Gulf of La Gonâve. Its tributaries flow eastwards and southwards through the Central Plateau. In the east, the Artibonite was impounded as Lake Péligre. Most other rivers are short and not navigable.[2]

ELECTRICITY SECTOR OVERVIEW

As of 2020, the total installed capacity in Haiti was reported to be 294 MW but no accurate official data are available. Approximately 78 per cent of the total, or 229.5 MW, was from thermal power plants, over 20 per cent, or 60.5 MW, was from hydropower and the remaining 2 per cent was from 3 MW of solar power and 1 MW of wind power (Figure 1).[5] A large majority of the installed capacity serves the country's capital and metropolitan area including the three largest thermal power plants — Carrefour I (50 MW), Carrefour II (34 MW) and E-Power (34 MW) — and the largest hydropower plant, Péligre (54 MW).[6,7] Another major thermal power plant is planned to be constructed in Carrefour and the large Varreux thermal power plant (68 MW) is in need of renovation. While these constructions take place, a Turkish company has been approved to install two barges, or floating power plants, with a combined capacity of 115 MW, near Varreux and Cap-Haitien.[8] Additionally, in 2021, funding was secured to be provided by the United States Agency for International Development (USAID) and the Inter-American Development Bank (IADB) to construct two new solar power plants in Carrefour with capacities of 8 MW and 4 MW.[9]

Figure 1. **Installed Electricity Capacity by Source in Haiti in 2020 (MW)**



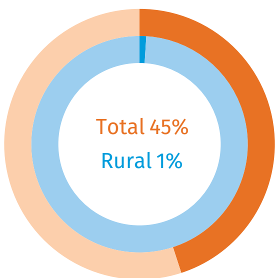
Source: CCREEE[5]

Due to infrastructural deterioration and technical inefficiencies, the actual available capacity is lower than what is installed and much of what is generated is lost. Total electricity generated in Haiti in 2020 was 2,199 GWh. Of this, approximately 380 GWh was sold and the remaining 1,319 GWh, almost 60 per cent, was considered lost.[5] This is due to widespread inefficiencies, and also to illegal connections to the grid that are not metered and, therefore, unbilled.[10]

Many households and businesses in Haiti generate their own electricity, most commonly with diesel units. While some use the generators as a back-up during blackouts, many have disconnected completely from the grid and fully rely on their own generators. The total capacity of electricity self-generated off the grid is unknown, but it exceeds the electricity generated on-grid. In 2017, it was estimated that over 75 per cent of total electricity generated within the country was from self-generation.[10]

In 2019, the overall electrification rate in Haiti was approximately 45 per cent and in rural areas it was just 1 per cent (Figure 2), the lowest in the western hemisphere.[11] Additionally, for the people that do have access to electricity, it is often only for some hours of the day rather than a 24-hour connection.

Figure 2. **Electrification Rate in Haiti in 2019 (%)**



Source: World Bank[11]

The electricity grid in Haiti consists of a number of isolated grids. Outside of the metropolitan area, there are 10 regional grids that serve the larger towns and nearby areas, as well as approximately 30 village-level grids.[12]

The principal company in the sector is Electricity of Haiti (EDH). By a decree of 20 August 1989 EDH was granted monopoly rights to generate, transmit, distribute and sell electricity across the country, but also allowed to outsource electricity production to independent power producers (IPPs). Another decree issued in 2006 allowed local communities not served by EDH to contract independent enterprises to provide electricity services, which fostered the development of micro-grids in the country. Historically there was no regulatory agency overseeing EDH activities until the National Authority for the Regulation of the Electricity Sector (ANARSE) was established in 2016, whose purpose is to guide the development of the electricity sector, in particular, through increasing the private sector involvement.[12]

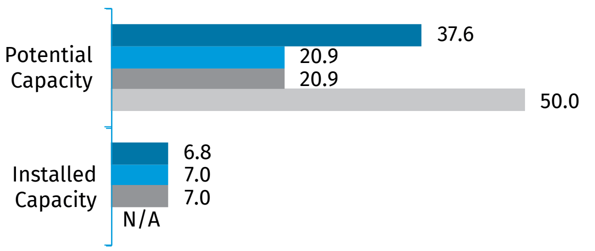
Electricity tariffs vary by consumer type. For residential customers the total tariff is 0.28 USD/kWh, for commercial customers it is 0.37 USD/kWh, for industrial customers it is 0.39 USD/kWh and for street lighting it is 0.37 USD/kWh.[5]

SMALL HYDROPOWER SECTOR OVERVIEW

There is no official definition of small hydropower (SHP) in Haiti. For the purposes of this chapter, all hydropower plants up to 10 MW will be classified as SHP.

In 2018, the total installed SHP capacity up to 10 MW in Haiti was 6.81 MW (Table 1).[13] Considering additional potential sites found in feasibility studies, total SHP potential in Haiti is 37.56 MW. Compared to the results of *the World Small Hydropower Development Report (WSHPDR) 2019*, installed capacity has slightly decreased and potential capacity has increased, both due to new available data (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Haiti (MW)**



Sources: Mitchell,[13] *WSHPDR 2019*,[14] *WSHPDR 2016*,[15] *WSHPDR 2013*[16]

There are currently eight hydropower plants in Haiti, all of which are operated by EDH. Seven plants are small-scale, while the only large-scale hydropower plant, the 54 MW Péligre plant, is the oldest hydropower plant in the country. Its first turbine out of three was commissioned in 1971 and it took three more years to complete the other two turbines. The most recently commissioned hydropower plant is an 11 kW micro-hydropower plant installed in the small community called Magazen, in the Nord-Est province, in 2016. This plant supplies electricity to 74 families.[14]

Over the years, the available capacity of the hydropower plants has decreased due to ageing equipment and lack of maintenance. In July 2018, with more than USD 100 million provided by the Inter-American Development Bank (IDB), the KfW Development bank and the Organization of the Petroleum Exporting Countries (OPEC) Fund for International Development, the biggest source of renewable energy in the country, the Péligre hydropower plant, regained its initial capacity of 54 MW.[14]

Source: Mitchell[13]

In addition to the existing SHP capacities, there are a significant number of sites identified with SHP potential that can be harnessed. According to the most recent feasibility study carried out by the Ministry of Public Works, Transport and Communication (MTPTC), there are 36 potential SHP sites ranging in capacity from 0.13 MW to 3.41 MW and with a combined untapped potential of 30.75 MW. The 20 potential sites with the largest capacities are shown in Table 2.[13]

RENEWABLE ENERGY POLICY

The development of the country's energy sector follows the Strategic National Plan for the Development of Haiti (SPDH), which envisages improving on-grid electricity services in urban areas and surroundings and supporting off-grid electrification in rural areas. The National Development Plan for the Energy Sector (2007–2017) recommended the promotion of renewable energy sources (wind power, solar power, biofuels) and the creation of an additional capacity from renewable energy sources of some 40 MW.[17] The plan also included objectives to increase electricity service for customers to have access 12 hours per day, to improve the regulatory role of the state and to create an environment that attracted foreign and domestic investment in the sector.[18] However, the 2010 earthquake, which damaged or destroyed a great number of electricity facilities, rendered the plan out-of-date and it has not been updated yet.

Nonetheless, the Government remains committed to the development of renewable energy sources in the country. In the country's First Nationally Determined Contribution of 2015, it set renewable energy goals for 2020 and 2030. By 2020, the goal was to install additional 37.5 MW in hydropower, which has not been achieved as of 2022. Conditional goals for 2030 include installing 20 MW of biomass, 30 MW of solar power, 50 MW of wind power and to add an additional 60 MW of hydropower, so that 47 per cent of the country's electricity sector is generated using renewable energy.[19]

In the country's 2017–2018 budget, measures for the promotion of renewable energy projects, particularly solar power, were introduced, including the elimination of import tariffs and duties on solar equipment. One of the objectives for the 2017–2018 fiscal year was to pursue the installation of solar power facilities across the country, particularly in areas with limited infrastructure, with a minimum of one installation per community.[20]

In 2017, the World Bank approved two grants for a total amount of USD 35 million, which will fund two projects in Haiti, Renewable Energy For All and Haiti Modern Energy Services For All. The projects aim to improve access to electricity and to scale up investments in renewable energy in underserved rural and urban areas. In particular, they will help:

- Improve the environment for private investment in renewable energy;
- Expand the access for rural households through leveraged investments in micro- and mini-grids and village level systems;

- Strengthen the capacity of local institutions and develop awareness of local communities on how to use renewable energy;
- Finance private operators, non-governmental and community organizations to provide solar lanterns and individual and home-based solar systems.[21]

As per the Decree on the Management of Environment and the Regulation of Citizen Conduct for Sustainable Development of 2005, all policies, plans and projects that would have a negative impact on the environment are subject to an environmental impact assessment (EIA). It also provides legal framework for various levels of government and their responsibilities towards the environment.[18]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The barriers hindering the development of SHP in Haiti include:

- Absence of a single decision-making authority and lack of coordination among government agencies and ministries;
- Absence of a legal framework aiming to facilitate private investment and technical rules facilitating connection between local grids;
- Limited funds for the construction of hydropower plants. The initial investment for the construction of a plant is considerably high, therefore, developers can be reluctant to invest;
- Lack of transmission infrastructure outside the capital metropolitan area and the cost of electricity system development is high.[14]

The key enablers for development of SHP in Haiti include:

- Most of the SHP potential is untapped and many sites have already been identified with their respective capacities;
- Being the least electrified country of the region, the necessity of developing power plants and supplying electricity is crucial, especially in rural or remote areas.

Jamaica

Kimberly Lyon, World Bank

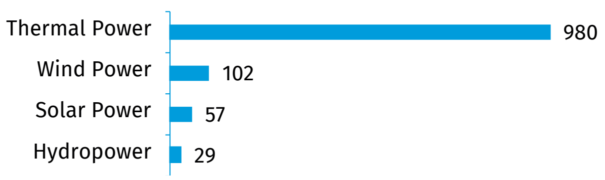
KEY FACTS

Population	2,734,092 (2019)[1]
Area	10,991 km^2[2]
Topography	The terrain of Jamaica is mostly mountainous, with a narrow, discontinuous coastal plain. The highest point is the Blue Mountain Peak at 2,256 metres above sea level and the lowest point is the Caribbean Sea.[2]
Climate	Jamaica has a tropical climate, which is influenced by the North-East Trade Winds, with a temperate climate in the interior. Average temperatures historically range from 24 °C to 27°C, varying with elevation and proximity to the coast.[3]
Climate Change	Jamaica has not experienced a significant increase or decrease in overall rainfall, but total annual precipitation is projected to decline starting in the mid-2020s due to climate change, with an onset of a more pronounced drying trend in the mid-2030s. The country is also grappling with the consequences of sea level rise. Current trends are projected to continue with possible temperature increases of 0.82-3.09 °C by the end of the century.[3]
Rain Pattern	Jamaica has a bimodal rainfall pattern, which translates into a dry season lasting from December to March and a rainy season from April to November. The mountainous interior generally receives annual rainfall in excess of 1,700 mm and the eastern part of the island receives up to 5,000 mm or more. The northern and southern coasts are significantly drier with the plains of the south receiving on average 1,000 mm of precipitation or less.[3]
Hydrology	The water resources of Jamaica consist of groundwater, captured in both limestone and alluvial aquifers, and surface water from over 100 rivers and streams. The central mountain ranges divide the catchment areas for rivers, which drain either to the northern or to the southern coasts. The island is divided into 10 hydrological zones. The limestone and alluvium aquifers provide 84 per cent of the country's freshwater resources, while the remaining 16 per cent is provided by surface water. The exploitable water resource is estimated at 3,930 MCM/year.[4,5] The main rivers include the Black River, Great River, Rio Cobre, Rio Grande, Rio Minho, Wagwater River and Yallahs River.[6]

ELECTRICITY SECTOR OVERVIEW

Electricity generation in Jamaica is dominated by fossil fuels with a growing contribution from renewable energy. At the end of 2019, Jamaica had 1,198 MW of available generation capacity, which generated 4,430 GWh of power (Figure 1). Of this total, the Jamaica Public Service (JPS) generated 1,229 GWh from steam and diesel, 1,055 GWh from gas and 155.2 GWh from small hydropower (SHP). Additionally, JPS purchased a further 1,990.3 GWh from independent power producers (IPPs) powered by wind power, solar power and oil.[7,8]

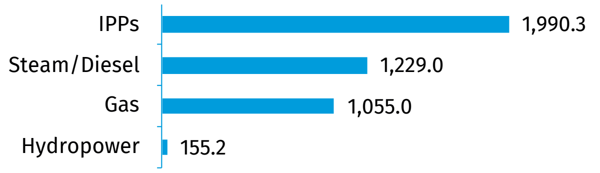
Figure 1. **Annual Electricity Generation by Source in Jamaica in 2019 (GWh)**



Source: JPS[7,8]

By the end of 2020, with the retirement of older units, there was 1,168 MW of available generation capacity.[7,9] Renewable sources made up almost 18.5 per cent of existing capacity and the remaining 81.5 per cent was fossil fuel-based, specifically, liquefied natural gas (LNG), heavy fuel oil (HFO) and automotive diesel oil. In 2020, the national power utility JPS continued with its plans to retire older fossil fuel plants and convert remaining steam generation assets to run on LNG. Thus, at the end of 2019, the island had 1,010 MW of thermal power capacity, while in 2020 this figure was reduced to 980 MW.[7] Wind power is the largest source of renewable energy at 102 MW, followed by solar power and hydropower at 57 MW and 29 MW, respectively (Figure 2).[10]

Figure 2. **Installed Electricity Capacity by Source in Jamaica in 2020 (MW)**



Source: JPS,[7] MSET[10]

The share of the population in 2017 with access to electricity stood at 94 per cent nationally with 98 per cent in the Kingston Metropolitan Area, 93 per cent in other towns and 91 per cent in rural areas. The vast majority of households get their electricity from the grid with only 0.1 per cent getting electricity from off-grid solar.[11] According to the World Bank, in 2019 over 99 per cent of the country's population had access to electricity, including 100 per cent in urban areas and almost 99 in rural areas.[12,13,14]

JPS is a vertically integrated power utility. It fully controls transmission and distribution of electricity on the island and owns 47 per cent of the power generation capacity, purchasing the remainder of its supplied electricity from IPPs, including Jamaica Energy Partners (JEP), Jamaica Private Power Company (JPPC), Jamalco and Wigton Wind Farm. The JPS was fully state-owned until 2001 when the Government of Jamaica divested 80 per cent of its shares to foreign investors. A small group of individuals hold 0.1 per cent of the JPS shares. In 2019, the Government announced its intention to list its remaining 19.9 per cent interest on the stock market. As of early 2021, the Government still retained its shares in the JPS.[9,15]

New generation capacity is added to the network through a competitive process and over 2015–2020, 117.3 MW of renewable energy capacity (wind power and solar photovoltaics (PV)) were added to the grid. The country's 2030 target for renewable energy penetration is 20 per cent of the total energy mix and 30 per cent of electricity generation.[10]

Electricity demand is expected to steadily grow over the coming decades with a forecasted annual growth rate of 1.3–1.6 per cent until 2035. By 2035, demand is projected to reach 5,865 GWh. Demand growth for both residential and commercial customers is expected to be driven largely by overall economic growth. JPS's load factor is assumed to remain constant at 78 per cent.[10]

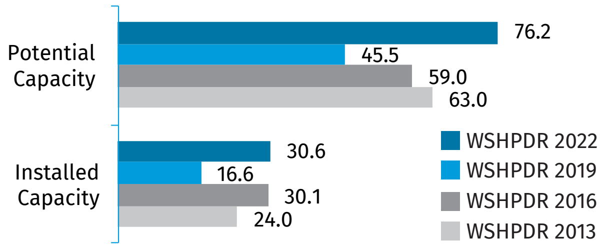
The average electricity tariff in Jamaica has trended downwards in recent years from 0.35 USD/kWh in 2013 to approximately USD0.27/kWh in 2020.[16,17] Nonetheless, it remains high due to the country's reliance on older, less efficient HFO generators that run on costly imported fuel as well as high losses in the transmission and distribution network. Because of its dependence on fuel imports, Jamaica remains very exposed to international price fluctuations. These factors, together with meeting the climate commitments, underpin the Government of Jamaica's strategy to increase the penetration of renewable energy in the energy mix and to transition the fleet of oil- and diesel-powered assets to run on LNG.[10,16]

The electricity sector is regulated by a multi-sector regulator, the Office of Utilities Regulation, which determines the electricity tariffs and oversees the net billing programme aimed at increasing renewable energy generation by small-scale intermittent sources (wind power and solar PV). With the rise of self-generation and other developments in the electricity sector, including the introduction of electric vehicles and the commissioning of a hybrid energy storage system, several new categories of tariffs were introduced in the JPS tariff determination for the period up to 2024. These include a distributed energy resource (DER) tariff for self-generation customers, an electrical vehicle tariff and a wheeling tariff.[17]

SMALL HYDROPOWER SECTOR OVERVIEW

SHP is not defined in Jamaican law or policy, but the threshold of 10 MW is commonly used by energy sector professionals and Government officials, with facilities below 1 MW considered mini-hydropower. All existing hydropower facilities and all but one proposed facility — the Mahogany Vale site — are under 10 MW.

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Jamaica (MW)**



Source: JPS,[7] MSET,[10] *WSHPDR 2019*,[19] *WSHPDR 2013*,[20] *WSHPDR 2016*[21]

There are eight existing hydropower plants in Jamaica (Table 1), all owned and operated by JPS. Together, these have an installed capacity of 30.6 MW and an annual generation of 152,612 MWh.[7,10] The existing hydropower fleet is fairly old with several facilities constructed before the country's independence in 1962. However, most facilities have been rehabilitated since the 1990s.[18] The most recent addition to the fleet is an extension project with a second powerhouse at the Maggoty Falls facility, which came online in 2014. The original Maggoty Falls facility was commissioned in 1966. Thus, no new SHP plants have been commissioned in Jamaica since the *World Small Hydropower Development Report (WSHPDR) 2019*. The change in the reported installed capacity is due to the fact that in the previous edition the

Maggoty Falls plants were counted as one and, hence, were excluded from the total due to their combined capacity exceeding 10 MW. However, the two Maggoty Falls plants have separate powerhouses and are treated by JPS as separate projects. The potential capacity estimate has also increased compared to the previous edition, based on new data on available sites (Figure 3).

Table 1. List of Existing Small Hydropower Plants in Jamaica

Name	*Location*	*Capacity (MW)*	*Head (m)*	*Plant type*	*Operator*	*Launch year*
Maggoty Falls Extension B	St. Elizabeth	7.2	88.4	Run-of-river	JPS	2014
Rio Bueno B	Trelawny	1.1	N/A	Run-of-river	JPS	1989
Ram's Horn	St. Andrew	0.6	N/A	Run-of-river	JPS	1989
Constant Spring	St. Andrew	0.8	N/A	Run-of-river	JPS	1989
Maggoty Falls A	St. Elizabeth	6.0	88.4	Run-of-river	JPS	1966
Lower White River	St. Ann	4.8	115.2	Run-of-river	JPS	1952
Roaring River	St. Ann	3.8	152.4	Run-of-river	JPS	1949
Rio Bueno A	Trelawny	2.5	89.9	Run-of-river	JPS	1949
Upper White River	St. Ann	3.8	70.1	Run-of-river	JPS	1945

Thirteen potential SHP sites have been studied for full-scale feasibility and deemed feasible. One site, Morgan's River, was studied at the pre-feasibility level but did not progress to full feasibility. The Rio Cobre (Angels) site is located at an existing irrigation weir operated by the National Irrigation Commission Ltd.[23,24,25] In the *WSHPDR 2019*, the 0.8 MW Dry River site was included in the list of potential SHP projects, however, in the current edition it has been removed as it was determined as not viable in a 2013 analysis by the Ministry of Science, Technology, Energy and Mining. Furthermore, the potential reservoir-based project Mahogany Vale with an estimated potential capacity of 50 MW has been foregone in favour of six small run-of-river projects in the same basin: Spanish River, Negro River, Yallahs River, Green River, Back Rio Grande and Swift River. The Back Rio Grande site (with a potential of 10–28 MW) appears to have been foregone in favour of four smaller projects: Swift River, Rio Grande 1, Rio Grande 2 and Back Rio Grande 2. Table 2 shows the available potential SHP sites.

Compared to other countries, the hydropower potential of Jamaica is considered low.[29] Based on the existing installed capacity and the identified potential sites, the country's economic SHP potential capacity and generation stand at 76.2 MW and 347 GWh per annum, respectively. The technical potential capacity and generation are estimated at over 80 MW and 600 GWh per annum, respectively.[30,31]

All the potential sites identified have been studied with a view to connecting them to the existing transmission and distribution network. There is little scope for off-grid SHP investments, but the law permits the development of micro-grids for rural electrification if JPS waives its right to provide service in a particular geography.[32]

Table 2. List of Potential Small Hydropower Projects in Jamaica

Name	*Location*	*Potential capacity (MW)*	*Head (m)*	*Type of site*
Great River	St. James	8.0	N/A	New
Spanish River	Portland	7.8	N/A	New
Martha Brae	Trelawny	4.4	N/A	New
Back Rio Grande 2	Portland	4.0	83.13	New
Swift River	Portland	2.9	54.9	New

Note: The project did not progress to the full feasibility study after the pre-feasibility study.

Efforts to promote SHP increased in the 2010s with the commissioning of pre-feasibility and feasibility studies for 11 sites ranging from 0.8 MW to 7.8 MW. There were plans to develop business plans for six of these sites to support their promotion to potential investors. However, in 2020, the Petroleum Corporation of Jamaica, the public entity responsible for energy planning and promotion, was dissolved and these responsibilities were transferred to the Ministry of Science, Energy and Technology.[33,34] The Ministry's latest Strategic Plan, covering the period of 2021–2025, affirms the Government's commitment to promoting renewable energy investments, including in SHP.[35]

The Government has demonstrated a preference for smaller hydropower projects over larger projects, considering potential social and environmental impacts as well as impacts on high-value tourism assets. This is evident from the decisions to pursue detailed investigation of multiple smaller projects in locations where there is potential for larger plants, specifically the proposed Mahogany Vale and Back Rio Grande projects.

SMALL HYDROPOWER PROJECTS AVAILABLE FOR INVESTMENT

There are several SHP projects available for investment above 1 MW that the Government intends to develop business plans for with the intention of investment promotion (Table 3).[33]

Table 3. **List of Selected Projects for Small Hydropower Projects Available for Development in Jamaica**

RENEWABLE ENERGY POLICY

Jamaica has a National Energy Policy covering the period from 2009 to 2030, which is aligned with the country's National Development Plan, Vision 2030. The aim of the plan is to create and advance a modern, efficient, diversified and environmentally sustainable energy sector, focused on diversification of the energy base towards indigenous sources of energy and clean technologies. The National Energy Policy is technology-neutral and promotes all renewable energy sources, including solar power, wind power, hydropower and biofuels.[18]

In 2020, the Government completed its Integrated Resource Plan (IRP), a 20-year roadmap for the country's electricity investment landscape. The IRP envisions 32 per cent of electricity generation by 2030 and 50 per cent by 2037 to be met with renewable energy sources. A total of USD 2.8 billion of investment is anticipated over the life of the IRP.[10]

The IRP also discusses the evolution of the national grid to accommodate higher integration of variable renewable energy sources with the ultimate goal of distributed markets for energy. However, the planning process for integrated distribution is only nascent, and the Government anticipates investing in further study and improvement of the integrated distribution planning framework. At present, any new investments in SHP would take the form of an IPP with a power purchase agreement with the JPS, the single buyer whose licence obligates it to purchase electricity from IPPs and persons with net billing arrangements.[32]

Over the planning horizon of the IRP, 485 MW of private power capacity has been identified for retirement and replacement, coinciding with their power purchase agreement expiration. Most of these are HFO-fuelled and JPS has a "right of first refusal" to do these replacements if it can be done more cheaply than by the proposed developer.[10] For JPS, the current allowed pre-tax weighted average cost of capital is set at 13.22 percent and for IPPs it is 11.16 per cent. At present, there are no feed-in tariffs, but the law empowers the Ministry with responsibility for energy, in consultation with the Office of Utilities Regulation, to set feed-in tariffs. There are no differentiated electricity prices based on technology or location.[32]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

According to the IRP, Jamaica is targeting 74 MW of new capacity to come from hydropower, waste-to-energy and/or biomass by the year 2025, increasing the share of hydropower in the generation mix from 2.8 per cent in 2020 to 4.4 per cent in 2037.[10]

All recent renewable energy investments to date have been made either fully by, or with significant participation of, the private sector, hence, it is not likely that the feasible potential SHP sites will be developed in the near term without a private sponsor. As JPS has indicated, it is not interested in pursuing further SHP developments and the Government will be targeting other local or foreign investors to implement these projects.[36]

New SHP projects would be governed by the same legislation and regulations as other energy technologies. There are no provisions in the Electricity Act specific to hydropower of any size. The licensing process for SHP involves securing the necessary land access rights; environmental permits issued by the National Environment and Planning Agency; a licence from the Water Resources Authority to use surface water; a power purchase agreement with JPS; a permit for interconnection, issued by the Office of Utilities Regulation; as well as permits from municipalities in which the generation assets would be located.[10,27]

COST OF SMALL HYDROPOWER DEVELOPMENT

A 2013 study by the Government indicated an average investment cost for SHP at USD 3.5 million per MW installed.[26] Investment costs of six recently studied SHP sites showed an average estimated investment cost of USD 4 million per MW installed or USD 1.28 million per GWh of energy produced. The most recently implemented project, the Maggotty Falls extension was completed in 2014 with an investment cost USD 36 million, which corresponds to approximately USD 5 million per MW installed.[37]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

The IRP indicates that the Government intends to analyze and develop incentives for SHP, however, such incentives have not been specified at this time. Jamaica has a vibrant financial sector, including a growing equities market and several commercial banking options more generally. There have been initiatives in past years, supported by international partners such as the World Bank, to incentivize renewable energy investments through credit lines.[38] Commercial banks have also made lower-interest loans available to small and medium enterprises and households for renewable energy investments. Several of the recent renewable energy installations have been made by overseas investors, qualifying for financing from foundations as well as development financing from their Governments.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The intensity and frequency of extreme rainfall events has shown an increasing trend over the last 70 years. While the whole island has experienced a small increase in total annual rainfall, variability has also increased with more consecutive wet days and dry days and more days recording extreme rainfall values. Portland, where several potential SHP sites are located, and Westmoreland have experienced the largest changes. Going forward, climate models project that average rainfall will decrease in Jamaica with a drying trend that will begin affecting the island in the mid-2020s. The island is projected to be up to 4 per cent drier by the 2030s and up to 10 per cent drier by the 2050s.[3] This will negatively impact river flows and decrease hydropower generation. Climate change and longer droughts are also expected to contribute to increased energy demand, though projections for energy demand are still largely driven by economic growth assumptions. All existing and proposed hydropower sites are run-of-river and thus have no inter-seasonal or inter-annual storage to help manage variability in flows. Future investments, particularly on the island's major rivers, will need to take into account the expected increase in extreme rainfall events.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

There has been very little activity in the SHP sector since the last set of Government-developed projects in the 1980s. Driven by efforts to lower the cost of electricity and transition the portfolio towards low-carbon indigenous sources of electricity, there has been a renewed interest in SHP development with new and updated studies having been completed in recent years.

The main barriers to SHP development in Jamaica are:

- Significant capital costs, which often exceed those for commercial-scale solar PV and wind power, and licensing requirements that involve a wider range of actors and regulators such as for the acquisition of land and water rights.
- Hydropower is widely perceived by sectoral actors as being very technically complex. The current sole operator of SHP assets in Jamaica is also not interested in further SHP development, instead favouring larger capacity installations with other technologies.
- Much of the knowledge of SHP development and operation is concentrated with JPS as the sole operator of SHP currently. Due to the limited activity in the sector over several decades, local contractors have virtually no experience in this specialized area. The island is heavily dependent on international engineers and consultants for SHP studies.
- Natural hydrologic variability. Many potential projects are located in the rainiest parts of the island, where the floods are so significant as to require significant infrastructure for safe control of releases.
- Disruptions in renewable energy planning and promotion. With the dissolution of the entity primarily responsible for energy planning in 2020 and the transfer of these responsibilities to the Ministry, activities aimed at promoting SHP development have been delayed or altered, including the development of business plans for selected SHP sites.

Nonetheless, in recent years, the enabling environment for SHP has become more favourable:

- The Government has invested considerably in new technical studies for SHP with the intention to develop business plans to support the promotion of selected sites as well as to develop an incentive structure to attract investors. Policy directives heavily favour indigenous renewable energy technologies, including SHP.
- The energy market of Jamaica is becoming more liberalized with the introduction of the 2015 Electricity Act (replacing the previous law enacted more than 125 years ago) and new licence structures.
- The Government has ambitious plans to modernize the energy system and significant investments in grid modernization have already been made by JPS.

Puerto Rico

Davy Rutajoga, International Centre on Small Hydro Power (ICSHP)

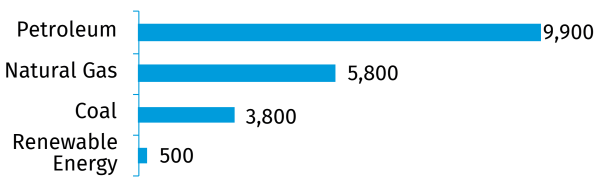
KEY FACTS

Population	3,193,694 (est. 2019)[1]
Area	8,870 km^2 [2]
Topography	Puerto Rico can be split into three physiographic zones. The mountainous interior area is formed by the Cordillera Central, the central mountain chain that transects the island from east to west. The highest point is Cerro de Punta at 1,338 metres above sea level. The second zone is the coastal lowlands that extend 10–19 kilometres inwards in the north and south. Finally, the karst region, consisting of formations of rugged volcanic rock, extends into the north of the island.[3]
Climate	The climate of Puerto Rico is tropical rainforest and temperatures throughout the year are warm to hot, between 22 °C and 25 °C. The temperatures in the southern coast are the warmest and a few degrees higher than in the north. In the central interior mountains, the temperatures are cooler than in the rest of the island.[4]
Climate Change	The 2017 Hurricane María, proven to have the greatest recorded 24-hour rainfall intensity in Puerto Rico since 1898, is among the extreme climatic events of the 2017 Atlantic Hurricane Season that can be attributed to climate change.[5] The subsequent increase in annual precipitations and rainfall intensity placed Puerto Rico first on the 2020 Global Climate Risk Index.[5] The Puerto Rico Climate Change Council reported a rise in average temperatures on the island as well as a rise in sea level and salinity of the ocean.[6] This represents a risk to the island's infrastructure as an estimated 25 per cent of it is located in coastal areas qualified as "easily flooded areas".[7] In particular, all thermal power plants on the island are located in the risky areas.[6]
Rain Pattern	The wettest month in Puerto Rico is August, with 180 mm of rain. Average rainfall varies across the island, ranging from 745 mm in the southern Isle of Maguey to 4,346 mm at Pico Del Este in the east. There is rainfall throughout the year, but it doubles from April to November, whereas the period between December and March is considered to be the driest.[8]
Hydrology	Puerto Rico has 224 rivers, with the main rivers draining the northern and southern areas. Due to the country's topography, there are no long rivers or large lakes.[7] The longest river that flows to the northern coast is the Grande de Arecibo. Other rivers include the La Plata, Cibuco, Loiza, Bayamon and Grande de Anasco.[3] Approximately 67 per cent of the surface drainage is from the central mountain ranges to the northern coast.[9]

ELECTRICITY SECTOR OVERVIEW

The main sources of energy in Puerto Rico are petroleum, natural gas and coal. In 2020, the total installed capacity was estimated at 5,839 MW, with 5,722.2 MW from fossil fuels and approximately 116.8 MW from renewable energy sources.[10] The total electricity generation of the island in 2020 was estimated at 20,000 GWh, with almost 50 per cent coming from petroleum, 29 per cent from natural gas, 19 per cent from coal and less than 3 per cent from renewable energy sources (Figure 1).[11] Average annual hydropower generation is estimated at 15.6 GWh. The natural gas is almost entirely imported as liquefied natural gas and the island has no proved reserves of crude oil or coal, both of which it imports from Colombia.[8]

Figure 1. **Annual Electricity Generation by Source in Puerto Rico in 2020 (GWh)**



Source: EIA[11]

Electricity in Puerto Rico is supplied mainly by the state-owned entity the Puerto Rico Electric Power Authority (PREPA). Average electricity tariffs for the three main groups of consumers are listed in Table 1.

Table 1. **Average Electricity Tariffs in Puerto Rico**

Type of consumer	*Average electricity tariff (USD/kWh)*
Residential	0.2326
Commercial	0.2594
Industrial	0.2288

Source: EIA[11]

In 2019–2021, the island was affected by a series of earthquakes, which culminated in a 6.4 magnitude earthquake that led to power outages by damaging electrical infrastructure. The aftershocks, estimated to recur for years after the earthquake, left two thirds of the population without power by considerably damaging the two largest power plants in Puerto Rico (EcoEléctrica and Costa Sur). As a consequence of the damage to these two natural gas-fired power plants, Puerto Rico had to shift its generation mix to rely more on petroleum, which went up to almost 50 per cent of the generation mix in 2020 from 35 per cent the previous year. Concomitantly, natural gas generation decreased to 20 per cent from 43 per cent in 2019 (Figure 2). Renewable energy generation was relatively unaffected by the earthquakes and remained stable. Power has been restored since and the island maintains an electrification rate of 100 per cent.[11]

The 2017 hurricanes damaged electrical infrastructure and led to PREPA privatizing its electricity transmission and distribution systems, as well as selling off some of its generation assets to avoid bankruptcy. The transmission and distribution systems have been operated by LUMA Energy, a private company, since June 2020.[11]

To strengthen the grid's resilience and avoid power outages, such as the ones the island experienced in the aftermath of the hurricanes of 2017, the Puerto Rico Energy Bureau issued its revised Integrated Resource Plan. Jointly with the plan, the Puerto Rico Energy Public Policy Act of 2019 (or Act No. 17 of 2019) outlines the country's commitment to sourcing 40 per cent of its electricity from renewable sources by 2025, eliminating coal-fired generation by 2028 and transitioning to 100 per cent renewable energy by 2050.[12,13]

SMALL HYDROPOWER SECTOR OVERVIEW

This chapter considers small hydropower (SHP) as plants with a capacity of up to 10 MW. There are seven SHP plants on the island with an aggregated capacity of 39.3 MW and an annual generation of 15.6 GWh. These are the 8.0 MW Yauco 2, 8.6 MW Toro Negro 1, 1.9 MW Toro Negro 2, 7.2 MW Garzas 1, 5.0 MW Garzas 2, 5.0 MW Rio Blanco and 3.6 MW Caonillas 2. However, four of these plants were inactive as of June 2021: Toro Negro 2 was offline awaiting testing, Garzas 2 was offline due to a faulty transmission line connecting it to the grid, Rio Blanco was offline awaiting replacement of the penstock and Caonillas 2 has been inactive since 1998 due to flooding from Hurricane Georges. This reduces the available capacity to 23.8 MW (Table 2).[14] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed capacity decreased due to the exclusion from the total of the inoperative Patillas plant (Figure 2).

The SHP sector of Puerto Rico has a potential capacity of 43.9 MW. The decrease in estimated potential capacity compared to the *WSHPDR 2019* comes after a re-evaluation of the hydropower system of Puerto Rico by the engineering firm Black & Veatch through a study commissioned by PREPA.[14]

Table 2. **List of Operational Small Hydropower Plants in Puerto Rico**

Plant name	*Installed capacity (MW)*	*Plant type*	*Operator*	*Launch year*
Toro Negro 1	8.64	Run-of-river	PREPA	1927
Yauco 2	8.00	Run-of-river	PREPA	1953
Garzas 1	7.20	Run-of-river	PREPA	1941

Source: Black & Veatch[14]

The United States Geological Survey (USGS) data have been analyzed to obtain the average discharge of the main rivers in Puerto Rico (44 in total).[18] Since all of the potential natural sites for larger reservoirs have already been used, the main potential growth area for SHP is micro-hydropower (units not exceeding 100 kW in capacity). The potential for micro-hydropower generation was determined using water flow and net head.[18] A net head range from 3 metres to 120 metres was considered due to variations from river to river or from location to location in the same river. The total micro-hydropower potential is approximately 3.1 MW (Table 3). This was the first attempt to estimate the micro-hydropower potential in Puerto Rico.[18] Not all potential sites were included in the estimate since many potential sites are not monitored.

Table 3. **Estimated Micro-Hydropower Potential in Puerto Rico**

Hydrologic unit	*Available potential (kW)*
Eastern Puerto Rico	1,148
Cibuco-Guajataca	1,067
Southern Puerto Rico	766
Culebrinas-Guanajibo	101
Total	**3,082**

SMALL HYDROPOWER PROJECTS AVAILABLE FOR DEVELOPMENT

The Black & Veatch study examined the need for refurbishment of the inactive plants and the improvement and modernization of the active plants. The study determined a need for a capital investment of approximately USD 140.5, million, which would result in a more than seven-fold increase in annual generation for a total potential generation of 112.7 GWh (Table 4) and a net present value (NPV) of USD 242.4 million over the 30-year period considered in the study (Table 5).[14]

Table 4. **List of Selected Small Hydropower Projects Available for Investment in Puerto Rico**

Plant name	*Installed capacity (MW)*	*Average annual generation without recommended improvements (MWh)*	*Potential capacity with recommended improvements (MW)*	*Average annual generation with recommended improvements (MWh)*	*Type of site (new/refurbishment)*
Caonillas 2	3.60	–	1.00	5,200	Refurbishment
Toro Negro 1	8.64	5,123	8.64	26,700	Refurbishment
Toro Negro 2	1.92	85	1.92	3,300	Refurbishment
Garzas 1	7.20	2,829	7.20	12,500	Refurbishment
Garzas 2	5.04	–	5.04	8,800	Refurbishment
Yauco 2	8.00	7,523	9.00	27,300	Refurbishment
Río Blanco	5.00	–	5.00	28,890	Refurbishment
Total	**40.40**	**15,560**	**37.80**	**112,690**

RENEWABLE ENERGY POLICY

Since 2010, in Puerto Rico local and foreign renewable energy businesses could choose between two incentive schemes: the Economic Incentives for the Development of Puerto Rico of 2008 and the Green Energy Fund (GEF) created by Act 83 of 2010.[19] The United States Energy Information Administration (EIA) provides some tax credits and incentives. Tax incentives include a 4 per cent fixed income rate for 15 years and a 90 per cent exemption from property taxes for 15 years. Tax credits can be up to 50 per cent to cover the expenses related to qualified research and development or to cover the cost of machinery and equipment for the generation and efficient use of energy for companies that produce their own power. Companies producing energy for domestic consumption can benefit from the GEF programme.

The GEF, worth USD 290 million and spanning over a 10-year period, supports three tiers of renewable energy projects.[20] Tier I, II and III targets correspond to residential and small businesses below 100 kW, mid-scale businesses between 100 kW and 1 MW and large-scale businesses over 1 MW, respectively.[20]

The Puerto Rico Sales and Use Tax Exemption for Solar Equipment, introduced in 2008, is a sales tax incentive that exempts taxes on solar power equipment and associated accessories and components.[21] Since 2019, the Energy Support Programme was introduced as a grant that aims to provide small and medium enterprises with USD 25,000 for the installation of renewable energy systems.[20]

Act 83 of 2010 introduced Renewable Energy Certificates (RECs). These are assets equivalent to 1 MWh generated from a green energy source. Starting in 2013, RECs could be bought, sold or transferred between entities. This enabled Puerto Rico to participate in the United States (US) renewable energy market. The RECs are also marketable abroad.[19]

The Renewable Portfolio Standard, created by Act 82 of 2010, set ambitious renewable energy production targets of 12 per cent by 2015, 15 per cent by 2020 and 20 per cent by 2035.[22] However PREPA failed to meet those targets with a total renewable energy generation reaching 3 per cent in 2020.[16] PREPA set new targets to derive 40 per cent of its electricity from renewable sources by 2025, 60 per cent by 2040 and 100 per cent by 2050.[11]

Act 57 of 2014, known as the Transformation and Energy Relief Act, created the Puerto Rico Energy Commission (PREC), an independent regulatory body overseeing PREPA's activities.[23] The commission is responsible for approving rate increases and urged PREPA to prepare a new Integrated Resource Plan aiming to optimize transparency and energy efficiency for electricity coming from fossil fuels and enable more renewable energy use at the distribution level. Under the updated Integrated Resource Plan, PREPA approved the refurbishment and modernization of the island's SHP plants.[12]

After Hurricane Maria struck Puerto Rico in September 2017, and the island's subsequent struggles to re-establish power over the territory, on 4 January 4 2018, the PREC released proposals emphasizing the role of renewable energy by establishing micro-grid installations.[17] The proposal defines that micro-grids must qualify as either renewable (at least 75 per cent of power from clean energy), combined heat-and-power or hybrid, and "shall consist, at a minimum, of generation assets, loads and distribution infrastructure". These are, by definition, owned by entities other than PREPA, but small cooperatives can interconnect with PREPA's grid by incurring a monthly fee of USD 25–250.[24] As part of the effort towards the development of micro-grids in Puerto Rico, the Rocky Mountain Institute (RMI) is collaborating with Fundación Comunitaria de Puerto Rico and Resilient Power Puerto Rico to assess the opportunity for resilient micro-grids on the island. This joint project is funded by the Rockefeller Foundation.[25]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

In Puerto Rico, SHP plants are regulated by some of the same legislation as larger hydropower projects. The main legislation and regulation documents concerning hydropower are:

- Puerto Rico Energy Public Policy Act (2019);
- Puerto Rico Electric Power Authority Act (1941);
- Puerto Rico Green Energy Incentive Law (2010).
- Legislation addressing SHP include:
- Hydropower Regulatory Efficiency Act (2013);
- Public Utility Regulatory Policies Act (1978);
- Federal Power Act (1920).

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

Many energy projects, including SHP, are funded by PREPA, which in turn receives funding from the Government of Puerto Rico and also, by extension, the US Government.[11] In addition to PREPA, the GEF provides funding for SHP projects in the form of rebates. For tier I projects (0–100 kW), rebates of up to 40 per cent of eligible costs are offered by the GEF on a first-come, first-served basis. For tier II projects (101 kW–1 MW), up to 50 per cent rebates are offered by the GEF through a quarterly competitive process.[19]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Due to increasingly frequent extreme climatic and seismic events such as the hurricane seasons of 2017 and 2019 and the series of earthquakes in 2020, electricity infrastructure in Puerto Rico has been considerably damaged. Many transmission lines were damaged, leaving a third of the population without electricity. These types of events resulting from climate change have already affected SHP in the past, with floods from Hurricane Georges damaging the Caonillas 2 plant in 1998. This plant was still awaiting refurbishment in 2021.

As most electrical infrastructure in Puerto Rico is situated in easily flooded areas, SHP plants are also threatened by the rising sea level, which could flood the island's coast. Finally, SHP plants in Puerto Rico are also affected by the limited water resources, which could worsen as irregular rainfall patterns have already been observed.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

In the short term, an increase in SHP generation could come from improvements in PREPA's existing hydropower units and also through micro-hydropower connected through net metering or in a stand-alone mode.[14]

There are, however, many barriers to SHP. The main ones include:

- A lack of finance: between PREPA and its bankruptcy, securing finance for any type of power plant will be difficult. Investment might also be difficult due to years of PREPA mismanagement;
- Limited SHP potential, compared with other renewable energy resources, in particular, solar, wind and

tidal power;
- Risk of severe weather events that could damage hydropower equipment;
- Lack of reservoir management. However, it is possible that if existing reservoirs were properly maintained, namely being dredged periodically, as well as if new generators were put in place and better water management were implemented, the potential for SHP could increase threefold;
- Limited water resources, which are used in the country mainly for human consumption;
- Some obstacles associated with micro-hydropower include little experience with this option in Puerto Rico and the division of regulatory oversight among local and federal (US) agencies, which does not present a clear permitting process for hydropower alternatives.[11,14]

Enablers for SHP development in Puerto Rico include:
- Government support for renewable energy in the form of subsidies for energy transition to renewable systems;
- Laws and regulations that support the development of SHP;
- PREPA's interest to refurbish and modernize SHP plants, including the commissioning of a study on the feasibility of refurbishment in 2021. This study produced a detailed report outlining the costs of improvement and the NPV in the long term;
- In 2021, the US Government rejoined the Paris Agreement, which implies a recommitment to investing in the fight against climate change and renewable energy, including hydropower and, by extension, SHP. With Puerto Rico being an unincorporated US territory, it stands to benefit from this recommitment to sustainable solutions.

Saint Lucia

Laura Stamm, International Center on Small Hydropower (ICSHP)

KEY FACTS

Population	183,629 (2020)[1]
Area	616 km^2[2]
Topography	An island of volcanic origin, Saint Lucia has a very rugged terrain. Jagged mountains of forested peaks and deep valleys, largely cover the interior of the country. In the south, the mountains tend to have even steeper slopes than in the north. The highest peak is Mount Gimie at 959 metres above sea level located towards the south-central region.[2]
Climate	Saint Lucia has a tropical maritime climate with little variation throughout the year. Temperatures typically range from 23 °C to 31 °C with an overall average of 27 °C at sea level. In higher elevations temperatures can dip to as low as 13 °C. While humidity remains above 70 per cent all year long, seasons are categorized by precipitation with a wet season between June and November and a drier season between December and May.[2]
Climate Change	Maximum temperatures in Saint Lucia have increased by over 1 °C since 1975 and the number of extremely hot days in a given year has also increased. This trend is expected to continue in the upcoming decades. Prevalence of hurricanes and overall windspeeds have increased but overall average rainfall per year has decreased within the past decades. As climate change continues into the future, natural disasters are expected to become more intense and the general climate is expected to become hotter and drier.[3]
Rain Pattern	Rainfall varies between seasons and elevation. Average rainfall is approximately 1,450 mm per year on the coasts near sea level and approximately 3,420 mm per year at higher altitudes in the interior. During the wet season from June to November, rain falls at a country-wide average rate of 200–250 mm per month, and between December and May usually less than 150 mm will fall per month. Occasional hurricanes are experienced during the wet season.[3,4]
Hydrology	There are 37 watersheds in Saint Lucia, of which 7 are of significance. These are the Roseau, Marquis, Cul-de-Sac, Fond D'Or, Troumassee, Cannelles and Vieux Fort Rivers. These rivers begin in the central region of high elevation and flow downwards to empty into the sea. The watersheds in the north of the island tend to be larger than those of the south, with the Roseau watershed being the largest.[4]

ELECTRICITY SECTOR OVERVIEW

At the end of 2020, total installed capacity in Saint Lucia was 91.6 MW with an available capacity of 88.4 MW that satisfied a peak demand of 59 MW. Most of the installed capacity, or 87.4 MW (over 95 per cent), was from the diesel-fuelled Cul-de-Sac power plant. A solar farm in La Tourney with an installed capacity of 3 MW and 1.23 MW of distributed solar photovoltaics (PV) rooftop panels feeding into the grid (under 5 per cent of the total) are the sources of renewable energy in the country (Figure 1).[5]

Figure 1. **Installed Electricity Capacity by Source in Saint Lucia in 2020 (MW)**

Source: LUCELEC[5]

Total electricity generation in Saint Lucia for the year 2020 amounted to 367.5 GWh, of which approximately 360.9 (98 per cent) was from diesel fuel and 6.6 GWh (2 per cent) was from solar power (Figure 2). Approximately 336.5 GWh was sold by the country's electricity company during the year. The residential sector consumed a total of 136.5 GWh and the commercial sector (excluding hotels) consumed 120.3 GWh. Hotels, usually one of the most important buyers of electricity in the country's tourism-dependent economy, consumed 51.5 GWh, which was an almost 40 per cent decrease from previous years due to the COVID-19 pandemic. The industrial sector consumed 17.8 GWh and street lighting used 10.3 GWh.[6] The sector experienced just under a 6 per cent loss of electricity for the year.[5]

Figure 2. **Annual Electricity Generation by Source in Saint Lucia in 2020 (GWh)**

Source: Department of Finance[6]

Access to electricity in Saint Lucia was over 99 per cent as of 2019.[7] St. Lucia Electricity Services Limited (LUCELEC) is the only electricity company in the country and is responsible for generation, distribution and transmission. It was created and granted sector exclusivity under the Ordinance No. 27 of 1964. The company was publicly owned until the passing of the Electricity Supply Act of 1994, which privatized its ownership but maintained its exclusivity. Currently, it is partially owned by several private entities with 10 per cent of its shares held by the Government of Saint Lucia.[8] The National Utilities Regulatory Commission (NURC) was created in 2016 as the electricity sector's regulatory body.[9]

Electricity tariffs vary based on consumer type and consumption level. Each group has a specified basic energy rate and then a standardized fuel surcharge is added. The basic rate is adjusted annually and the fuel surcharge is adjusted monthly based on global fuel prices. Table 1 shows the electricity tariffs for each type of customer as of April 2022.[10]

Table 1. **Electricity Tariffs by Consumer in Saint Lucia in April 2022**

Type of consumer	Usage	Basic energy rate (USD/kWh)	Fuel surcharge (USD/ kWh)	Final tariff rate (USD/ kWh)
Domestic	1–180 units	0.27	0.087	0.36
	> 180 units	0.29	0.087	0.38
Commercial	Low tension	0.33	0.087	0.42
	High tension (bulk)	0.31	0.087	0.40
Industrial	Low tension	0.33	0.087	0.42
	High tension (bulk)	0.31	0.087	0.40
Street lighting	All units	0.33	0.087	0.40

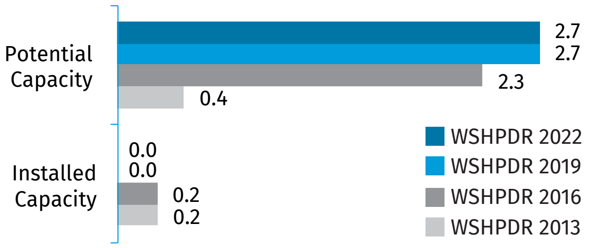
SMALL HYDROPOWER SECTOR OVERVIEW

As there is no local definition for small hydropower (SHP) in Saint Lucia, in this chapter it is defined as plants with a capacity of up to 10 MW.

While potential capacity is estimated at approximately 2.68 MW, there were no hydropower plants in operation in the country as of 2022. There was an SHP plant in Latille Falls constructed in 2006 with a capacity of 240 kW, however, it has been years since it was severely damaged by a hurricane and is no longer in operation.[11] Most recently, a feasibility study of a potential hydropower site at the John Compton Dam on the Roseau River was carried out by a German consultancy organization in 2015. Although the study confirmed a possibility of an SHP plant of 336 kW and deemed it technically and economically feasible, no official plans to construct it have been announced as of yet.[12] Without new discoveries of potential capacity or construction of new plants in the past few years, the information remains the same since the last publication of the *World Small Hydropower Development Report (WSHPDR)* in 2019 (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Saint Lucia (in MW)**



Sources: *WSHPDR 2019*,[13] *WSHPDR 2016*,[14] *WSHPDR 2013*[15]

There are no local financial mechanisms specifically aimed at supporting SHP projects. However, there may be opportunities to receive support through renewable energy projects being developed by the Government of Saint Lucia.

RENEWABLE ENERGY POLICY

The country's first legislation that mentions renewable energy was the Electricity Supply Act of 1994. LUCELEC was privatized in this act with the aim that outside sources would provide financial funding for renewable energy development and the act provided voluntary financial incentives for it. In 1999, the Government of Saint Lucia announced that exemptions for import and consumption taxes would be given to developers of renewable energy but no institutional or regulatory framework was created to enforce it.[2,16]

Over a decade later, the National Energy Policy of 2010 was established in order to create an enabling regulatory and institutional environment towards increasing the renewable energy share in the energy mix. It set a goal to achieve a 5 per cent share of renewable energy in the mix by 2013, a 15 per cent share by 2015 and a 30 per cent share by 2020. Due to its non-intermittent nature and large potential, the plan favoured the development of geothermal energy to satisfy the base-load demand of electricity, but recognized the importance of all types of renewable energy. It granted grid preference to any type of renewable energy that would be available over fossil fuels, on the condition that the energy stability would not be compromised.[16] As of 2022, the goals that were set in this plan have not been reached.

In 2017, the Government and LUCELEC published the forward-looking National Energy Transition Strategy. This outlined possible scenarios of what the country's energy sector could look like in 2025, ranging from a 0 per cent share of renewable energy to an over 75 per cent share of renewable energy. Each scenario was tested on grounds such as potential future incurred debt, operational costs and external shocks such as high oil prices. Considering the country's economic standing it was found that the optimal strategy would be to install 30 MW of solar power and 12 MW of wind power by 2025. It was also recognized that unless foreign capital is used for geothermal energy development, it is not feasible for domestic investment despite the fact that it would be necessary to achieve the scenario of an over 75 per cent share of renewable energy.

In January 2020, LUCELEC made plans to set groundwork for a smart grid as well as to work towards the installation of a 10 MW solar power system and a 12 MW wind farm. These projects have since been put on hold due to the COVID-19 pandemic.[5]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The main barriers to SHP development in Saint Lucia include, but are not limited to:

- The generally low baseflows of the main rivers, which are unable to support hydropower plants;
- Other renewable energy sources, particularly solar power and wind power, are given a higher priority in the Government's policies and development plans, and in public and private sector projects.[13]

The key enablers for SHP development in Saint Lucia are:

- The positive feasibility study of SHP on the Roseau River that has not been taken advantage of;
- Inclusion of hydropower would lessen the country's over 90 per cent reliance on diesel and could help reach the set renewable energy goals.

Saint Vincent and the Grenadines

Davy Rutajoga, International Center on Small Hydro Power (ICSHP)

KEY FACTS

Population	110,947 (2020)[1]
Area	389 km^2[2]
Topography	The country consists of the main island, Saint Vincent, and a chain of 32 smaller islands, the Grenadines. Saint Vincent is a mountainous, volcanic island, located north of Trinidad and Tobago. It borders the Caribbean Sea in the west and the Atlantic Ocean in the east. The highest point is Soufriere, an active volcano with an altitude of 1,234 metres. Steep slopes and rugged landscapes comprise the remaining territory of Saint Vincent Mount Tobai, on Union Island, is the highest point in the Grenadines, with an altitude of 308 metres. The topography of the Grenadines is characterized by beaches and shallow bays.[3]
Climate	The climate of Saint Vincent and the Grenadines is tropical, characterized by increased humidity and uniform temperatures throughout the year. The average annual temperatures are estimated at 27 °C. September is the hottest month, with temperatures reaching an average of 29 °C. February is considered the coldest and windiest month. Winds in February reach on average 23 km/h and the average temperature is 25 °C.[4]
Climate Change	Saint Vincent and the Grenadines is affected by extreme climatic events associated with climate change, particularly, due to the country's location within the Atlantic hurricane belt. Some of these are intense hurricanes, such as the Hurricanes Ivan and Thomas of 2004 and 2010, respectively. The country is also experiencing warmer days and nights, unpredictable and reduced rainfall, droughts, floods, landslides, coral bleaching with rising ocean temperatures and coastal erosion.[5] The mean annual temperature is predicted to keep increasing at an average rate of 0.15 °C per decade. Rainfall is predicted to decrease, with negative median values of between 15 per cent and 22 per cent annually by the 2090s.[6]
Rain Pattern	The annual precipitation in Saint Vincent and the Grenadines is estimated to be between 1,500 mm and 6,000 mm.[7] Precipitation has seen a decline of approximately 8.2 mm per month per decade since 1960.[8] Rainfall is an important source of freshwater for the Grenadines and this decline is likely to affect water resources in the region.
Hydrology	There are no navigable rivers in Saint Vincent and the Grenadines, most of them being short and straight. The Colonaire is the longest river in the country. Other important rivers are the Buccament, Cumberland and Warrowarrow.[9] River defences were planned to be constructed on the Colonaire, Buccament, Cumberland and Warrowarrow by the Government of Saint Vincent and the Grenadines in collaboration with the Canada Caribbean Resilience Facility (CRF) as part of the Disaster Vulnerability Reduction Project (DVRP).[10]

ELECTRICITY SECTOR OVERVIEW

The main sources of electricity in Saint Vincent and the Grenadines are petroleum and hydropower. The country is heavily reliant on imported petroleum, which accounted for approximately 83 per cent of the 150.8 GWh of electricity generated in the country in 2020. Hydropower accounted for less than 15 per cent and solar power accounted for less than 3 per cent of the generated electricity (Figure 1).[11] The installed capacity in the country in 2020 was 54 MW, with over 85 per cent from petroleum, over 11 per cent from hydropower and over 3 per cent from solar power (Figure 2).[11] The electricity in Saint Vincent and the Grenadines' islands of Bequia, Canouan, Mayreau and Union is generated, transmitted and distributed by Saint Vincent Electricity Services Ltd (VINLEC), which owns the monopoly in the region. Electricity on Mustique Island is produced by Mustique Company Ltd. Total access to electricity is estimated at 100 per cent.[11,12]

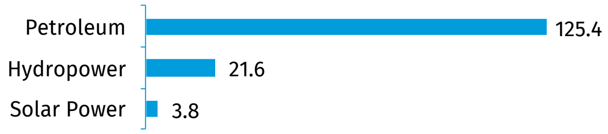
Source: Statistical Office[11]

Figure 2. **Installed Capacity by Source in Saint Vincent and the Grenadines (MW)**



Source: Statistical Office[11]

The electricity in Saint Vincent and the Grenadines is regulated by VINLEC and the Cabinet of the Government of Saint Vincent and the Grenadines. VINLEC uses networks spanning over 563 kilometres to provide electricity to customers. It became a fully state-owned enterprise in 1985 after being incorporated in 1961 and selling an initial 49 per cent of its shares to the Government in 1971.[13]

In order to assist in formulating and implementing policies related to energy as well as coordinating specific activities related to renewable energy and energy efficiency initiatives, the Government of Saint Vincent and the Grenadines created the Energy Unit.[14]

The average electricity tariffs for the four main groups of consumers are listed in Table 1. According to VINLEC, a value-added tax (VAT) of 16 per cent is applicable to domestic customers who consume more than 150 kWh. This tax is also paid by all commercial and industrial customers.[15]

Table 1. **Average Electricity Tariffs in Saint Vincent and the Grenadines**

Type of consumer	*Average electricity tariff (USD/kWh)*
Residential	0.19
Commercial	0.20
Industrial	0.16
Street lighting	0.21

SMALL HYDROPOWER SECTOR OVERVIEW

The definition used by the country for small hydropower (SHP) is up to 10 MW. The installed capacity of SHP in Saint Vincent and the Grenadines is estimated at 5.7 MW and comes from three plants: the South Rivers, Richmond and Cumberland hydropower plants.[12] However, their capacity is not available at full scale year-round, with the available capacity decreasing to approximately 2 MW during the dry season, which creates the need to use diesel plants for back-up.[17] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, the SHP installed capacity decreased based on more accurate data (Figure 3). The total SHP potential is estimated to be 7.5 MW.[12]

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Saint Vincent and the Grenadines (MW)**

Table 2. **List of Operational Small Hydropower Plants in Saint Vincent and the Grenadines**

Name	*Installed capacity (MW)*	*Plant type*	*Operator*	*Launch year*
Cumberland	3.65	Run-of-river	VINLEC	1987
Richmond	1.10	Run-of-river	VINLEC	1962
South Rivers	0.96	Run-of-river	VINLEC	1952

Source: VINLEC[21]

A study for the rehabilitation of the Richmond plant and the expansion of South Rivers plant was conducted in 2009. Due to favourable findings, VINLEC was prompted to undertake modernization and refurbishment projects at both plants. The first such initiative commenced in 2013 and the refurbishment works at the Richmond and South Rivers plants were completed in 2016 and 2018, respectively.[21] VINLEC also considered developing another power plant of 1.2 MW downstream South Rivers, on the Colonarie, but no updates on progress are currently available.

RENEWABLE ENERGY POLICY

The cost of energy in Saint Vincent and the Grenadines is relatively high. However, there is significant potential for the adoption and implementation of renewable energy. In order to address sustainability issues, the Government established the National Energy Plan (NEP) in 2009. In 2010, an additional document, the National Energy Action Plan (NEAP), provided more accurate details with regards to the initiatives both the public and the private sector will undertake to promote the dissemination of renewable energy projects in the country.[22]

While the National Energy Action Plan (NEAP) specified a diverse variety of measures for implementation and even designed short- and long-term targets, it has not been successful in achieving the set target of 60 per cent of electricity output produced through renewable energy by 2020.[11]

Although the country's potential is high, more financial and construction policies to motivate and accommodate investors are needed.

In addition to these policies, the country has also implemented feed-in tariffs (FITs), tax reductions and exemptions for the usage of renewable energy and green public procurement.

VINLEC has also undertaken multiple studies to evaluate the feasibility of investing in renewable energy. Some of the projects that the company is considering or recently completed in collaboration with the Government of Saint Vincent and the Grenadines are outlined below:

- Ribishi Point was identified as a suitable site for the development of wind power after a 2005 study conducted by VINLEC, however, the project stalled due to the proximity to the new airport and scaling down of the project is currently being explored; other locations, including some of the small Grenadines islands, are also being considered;
- The installation of solar panels on a car park canopy and the roofs of the transformers and back-up generator sheds at the Cane Hall Engineering Complex for a total capacity of 30 kW;
- A 370 kW solar PV plant installation project was commissioned at the Lowmans Bay Power Station in 2014 and is operational;
- A joint project with Emera Caribbean Inc. and Reykjavik Geothermal to develop the geothermal potential of the island; however, the project has been challenged by the lack of sufficient permeability of the resource tapped by the wells drilled;
- Generating electricity through the recovery of heat from waste is another measure that the Government of Saint Vincent is considering.[12,17,23,24,25]

The Regional Disaster Vulnerability Reduction Project is a USD 23 million project conceived in 2011 and aiming, among other things, to strengthen river embankments in Saint Vincent and the Grenadines. As part of this project, coastal areas and infrastructure are to be protected from climate change-related damage, thus ensuring the safety of hydropower plants. The final phase of the implementation of this project, set for December 2020, was hindered by the travel restrictions imposed to curb the spread of COVID-19.[26]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

SHP plants are regulated by some of the same legislation as larger hydropower plants. The main legislation and regulation documents in Saint Vincent and the Grenadines concerning hydropower are:

- The Electricity Supply Act (1973);
- Hydroelectric Ordinance No. 24 (1951).

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

There are numerous barriers to SHP development Saint Vincent and the Grenadines, including:

- No specific plan on SHP development has been defined;
- Despite the attempts to encourage investment in renewable energy, the market is still heavily reliant on fossil fuels for electricity production;
- VINLEC's monopoly may prevent smaller private companies from effectively developing and implementing renewable energy projects at profitable rates;
- Limited potential for SHP development, particularly on the smaller islands;
- Seasonal rainfall variability affects SHP as hydropower availability can decrease by 50 per cent or more during the dry season;
- SHP is no longer a priority for the Government, with most investment being focused on the development of solar and geothermal power.[27]

The factors that favour further SHP development in the country include:

- The Government has been actively promoting renewable energy solutions and has implemented initiatives to raise awareness of the efforts made by the country to embrace renewable energy and the potential for further investment;
- The Government has been increasingly promoting small-scale sustainable energy projects as well as the introduction of electric vehicles;
- Availability of incentives in the form of FITs, tax reductions and exemptions for the usage of renewable energy;
- Availability of financial and capacity building support from international institutions, such as the Global Environment Facility (GEF), World Bank, International Renewable Energy Association (IRENA), etc.[12,28,29]

2.2. Central America

Countries: Belize, Costa Rica, El Salvador, Guatemala, Honduras, Mexico, Nicaragua, Panama

INTRODUCTION TO THE REGION

The electricity sectors of countries in Central America are marked by a relatively high degree of diversification, high electricity access and significant involvement of private companies. Fossil fuels are the leading source of electricity generation in Guatemala, Mexico and Nicaragua. In other countries in the region fossil fuels generally play a supporting role, with thermal power capacities held in reserve to supplement variable generation from renewable energy sources (RES). For example, in Belize, thermal power from fossil fuels accounted for just 9 per cent of annual generation in 2020. Nearly all major RES are well-established in the region, including hydropower, solar power, wind power and bioenergy. This also includes geothermal power, which is widely used across Central America and plays a particularly important role in the electricity mix of El Salvador and Nicaragua.

Central America is well-supplied with hydropower resources, and hydropower is the leading RES in the region by installed capacity. Mexico accounts for the largest share of regional hydropower capacity, while Belize and Costa Rica have the highest proportion of their installed capacity provided by hydropower. Although nearly all countries in the region rely on hydropower to a significant extent, the interannual and seasonal variability in generation from hydropower in the region requires the maintenance of significant reserve capacities provided by other energy sources.

Private companies play a major role in the production of electricity in the region. During the 1990s, most countries in the region underwent a period of liberalization and privatization in the energy sector, with state-owned energy companies including electricity producers, providers and companies in the oil and gas sector undergoing unbundling and partial or full privatization. The process of electricity sector privatization has continued through the first two decades of the 21st century but has generated increasing opposition, particularly in Mexico. Among the countries in the region, the electricity sectors of Honduras and Guatemala are the most fully privatized, with private companies operating 80 per cent and 86 per cent of these two countries' respective electricity capacities. In other countries, the share of installed capacity operated by private companies is in the 20–50 per cent range.

The degree of interconnectivity in the region is very high, with El Salvador, Costa Rica, Guatemala, Honduras Nicaragua and Panama all connected to the Central American Electric Interconnection System (SIEPAC). The Mexico-Belize interconnection is likewise important and provides Belize with roughly a third of its electricity supply. Mexico has additional interconnections with Guatemala as well as with the United States of America on its northern border, while Panama shares interconnections with its southern neighbour Columbia.

An overview of the electricity sectors of the countries in the region is provided in Table 1.

Table 1. **Overview of Central America**

Country	*Total population (million people)*	*Electricity access, total (%)*	*Electricity access, rural (%)*	*Total installed capacity (MW)*	*Electricity generation (GWh/year)*	*Hydropower installed capacity (MW)*	*Hydropower generation (GWh/year)*
Belize	0.4	93	88	132	433	55	242
Costa Rica	5	99	N/A	3,566	11,313	2,343	7,827
El Salvador	7	98	95	2,360	5,388	574	1,985
Guatemala	17	92	N/A	3,993	12,224	1,560	4,381
Honduras	10	85	71	2,830	10,888	849	3,765
Mexico	126	100	100	87,894	317,820	12,614	23,602
Nicaragua	7	88	74	1,620	3,797	157	575
Panama	4	96	88	4,128	10,887	1,810	7,226
Total	-	-	-	**106,523**	-	**19,961**	-

Source: WSHPDR 2022[1]

Note: Data in the table are based on data contained in individual country chapters of the WSHPDR 2022; years may vary.

REGIONAL SMALL HYDROPOWER OVERVIEW

There is no universally-accepted definition of small hydropower (SHP) in Central America. Honduras defines SHP as hydropower plants with an installed capacity of up to 30 MW. El Salvador and Guatemala adhere to the up to 5 MW definition, in line with the definition proposed by the Latin American Energy Organization (OLADE), while Nicaragua uses the up to 10 MW definition. No official definition of SHP exists in Belize, Costa Rica, Mexico or Panama, although Panama provides incentives for hydropower plants of up to 20 MW without classifying such plants as SHP, and Mexico uses the up to 30 MW definition for the purpose of incentivization.

A comparison of installed and potential SHP capacities in the region is provided in Table 2.

Table 2. **Small Hydropower Capacities by Country in Central America (MW)**

Country	*Local SHP definition*	*Installed capacity (local def.)*	*Potential capacity (local def.)*	*Installed capacity (≤10 MW)*	*Potential capacity (≤10 MW)*
Belize	N/A	N/A	N/A	10.3	21.7
Costa Rica	N/A	N/A	N/A	126.5	126.5*
El Salvador	Up to 5 MW	21.7	N/A	21.7	119.6
Guatemala	Up to 5 MW	123.0	204.9	123.0**	204.9**
Honduras	Up to 30 MW	288.6	N/A	148.0	385.0
Mexico	N/A	699.3***	N/A	N/A	N/A
Nicaragua	Up to 10 MW	26.6	104.7	26.6	104.7
Panama	N/A	N/A	N/A	147.2	263.5
Total	-	-	-	**603.3**	**1,225.9**

Source: WSHPDR 2022[1]

Note: *Based on installed capacity. **Based on the local definition of SHP. ***Based on the up to 30 MW definition of SHP.

The total installed capacity of SHP up to 10 MW in Central America is 603.3 MW, while estimated potential capacity is 1,225.9 MW. Relative to the World Small Hydropower Development Report (WSHPDR) 2019, the installed capacity has increased 15 per cent due to ongoing SHP development in several countries in the region, including Guatemala, Honduras, Nicaragua and

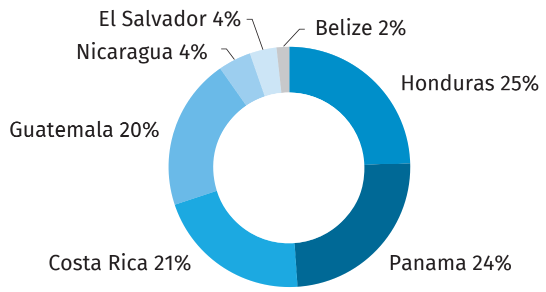
Panama. Meanwhile, the estimate of potential capacity has increased by approximately 2 per cent, mainly as a result of more recent data on the estimated potential SHP capacity of Nicaragua.

Mexico is the regional leader in SHP capacity based on the SHP definition of up to 30 MW, but even under this definition SHP accounts for only a small share of the country's total hydropower capacity. By contrast, SHP accounts for 17 per cent of all hydropower capacity in Nicaragua, 17 per cent in Honduras and nearly 19 per cent in Belize. Guatemala, Honduras, Nicaragua and Panama have all seen significant increases in total installed SHP capacity in recent years. Factors that have contributed to SHP development in these countries include state-supported incentive schemes as well as funding provided by international development programmes. In Belize, Costa Rica, El Salvador and Mexico, little recent SHP development has taken place.

Challenges faced by the SHP sector in the region require a comprehensive response. In particular, climate change is emerging as a major barrier to SHP development, and needs to be addressed through appropriate planning and adaptation measures, particularly in the case of prolonged drought. Climate change response in the region requires a more effective model of public-private-community collaboration, including the introduction of integrated watershed management that would provide a platform for local communities to fully participate in the decision-making and profit-sharing aspects of SHP construction and operation.

The national share of regional installed SHP capacity by country is displayed in Figure 1, while the share of total national SHP potential utilized by the countries in the region is displayed in Figure 2.

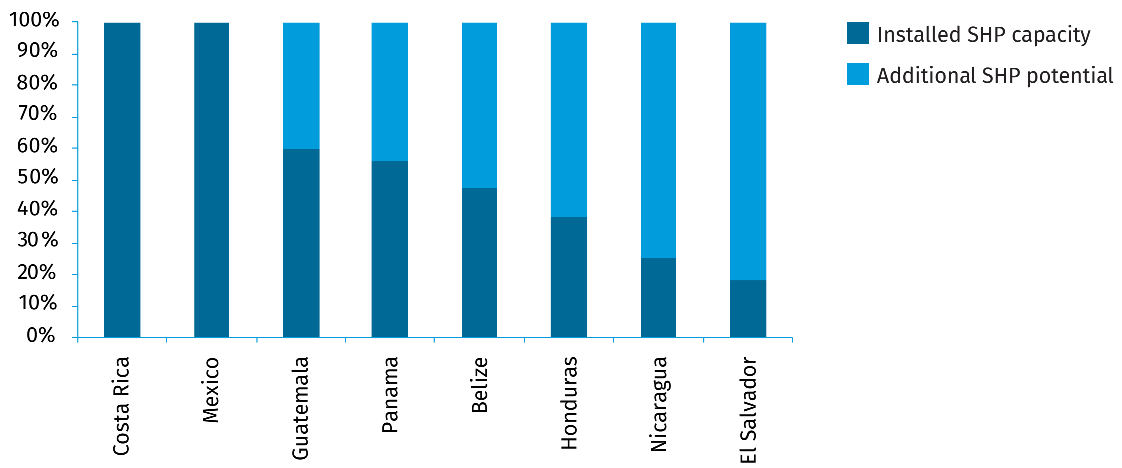
Figure 1. **Share of Regional Installed Capacity of Small Hydropower up to 10 MW by Country in Central America (%)**



Source: WSHPDR 2022[1]

Note: Mexico not included due to lack of data on SHP up to 10 MW.

Figure 2. **Utilized Small Hydropower Potential by Country in Central America (%)**



Source: WSHPDR 2022[1]

Note: For SHP up to 10 MW except in the case of Mexico, where the up to 30 MW definition is used, and Guatemala, where the local definition is used. For Costa Rica and Mexico, all SHP potential is assumed to be utilized due to a lack of reliable estimates of potential capacity.

The installed capacity of SHP up to 10 MW in **Belize** is 10.3 MW, provided by two SHP plants, and has not changed since the commissioning of the second plant in 2005. The potential capacity is estimated at 21.7 MW, indicating that approximately 47 per cent has been developed. The most recent study of SHP potential was carried out in 2006. Since then, no additional activity related to the SHP sector has taken place.

In **Costa Rica**, the installed capacity of SHP up to 10 MW is 126.5 MW, while the estimate of potential capacity is 7,373.5 MW, indicating that approximately 2 per cent has been developed. No new SHP construction has taken place in the country in recent years, although the assessed installed capacity has been revised upwards due to access to better data on existing SHP plants. The estimate of potential SHP capacity in the country is provided on the basis of a 2017 study assessing worldwide hydropower potential.

In **El Salvador**, there are 17 operational SHP plants with a total installed capacity of 21.7 MW, in addition to two plants with a capacity of 0.63 MW that are likely decommissioned or in need of extensive repairs. All existing SHP plants in the country have an installed capacity under 5 MW, and there are no plants in the 5–10 MW capacity range. The potential capacity for SHP up to 10 MW has been estimated at 119.6 MW, of which 18 per cent has been developed. There are two ongoing SHP projects on the San Simon River.

There are 65 operational SHP plants of up to 5 MW in **Guatemala** with a total installed capacity of 123 MW. An additional 33 plants with a total capacity of 80 MW are registered with the Government but are not operational, and one SHP plant with a capacity of 1.9 MW is pending registration. On the basis of these capacities, total potential SHP capacity of up to 5 MW in Guatemala is estimated at 204.9 MW, of which 60 per cent has reached operational status. The undeveloped SHP potential of the country is likely to be higher but no reliable estimate is available.

In **Honduras**, the installed capacity of SHP of up to 30 MW is 288.6 MW provided by 45 plants, of which 37 are plants of up to 10 MW and with a combined capacity of 148 MW. Potential capacity for SHP up to 10 MW is estimated at 385 MW, indicating that 38 per cent has been developed. The installed SHP capacity of the country has been growing steadily over the last decade due to the construction of new plants, but no data on ongoing SHP projects are available.

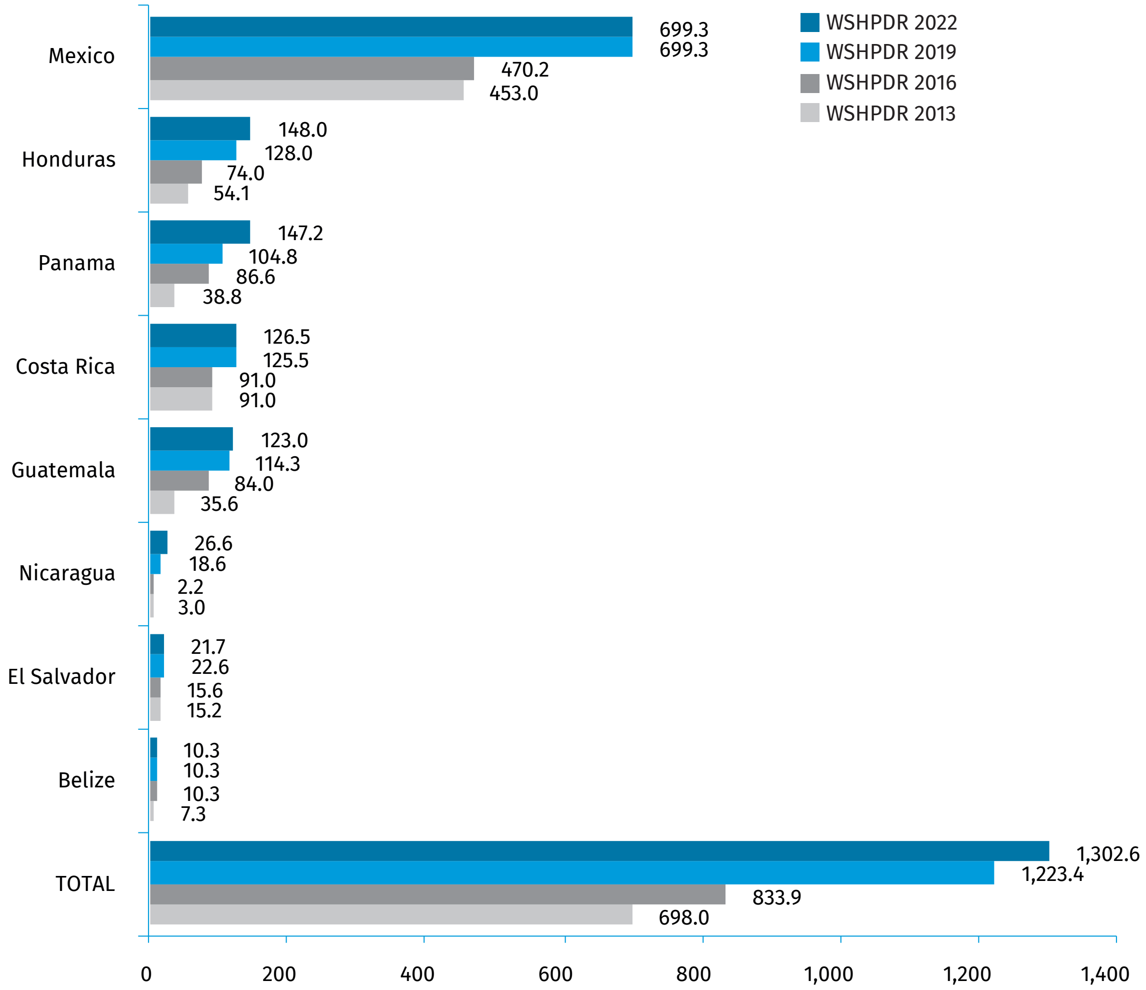
The installed capacity of SHP up to 30 MW in **Mexico** is 699.3 MW, provided by 69 plants. There is no reliable estimate of potential SHP capacity in the country. A large number of studies of SHP potential have been carried out over the last few decades in different parts of the country, producing estimates that differed by a wide margin. At the high end, one study suggested the existence of over 3,000 potential micro-, mini- and small hydropower sites across the country. In addition to existing SHP plants, 41 SHP plants were under construction across the country as of 2021, with a combined planned capacity of 452.5 MW.

There are 17 operational SHP plants of up to 10 MW in **Nicaragua** with a total installed capacity of 26.6 MW. Based on an inventory of 20 potential SHP sites, potential capacity for SHP of up to 10 MW is estimated at 104.7 MW, indicating that 25 per cent has been developed. Three new SHP plants have been constructed in the country in recent years and several additional potential sites have been identified.

The installed capacity of SHP of up to 10 MW in **Panama** is 147.2 MW provided by 24 operational SHP plants, while potential capacity is estimated at 263.5 MW, indicating that 56 per cent has been developed. The installed SHP capacity of the country has expanded considerably over the last few years. There were 9 additional plants under construction as of 2021 and 13 other potential SHP sites have been identified.

Changes in the installed SHP capacities of the countries in the region compared to the previous editions of the WSHPDR are displayed in Figure 3.

Figure 3. **Change in Installed Capacity of Small Hydropower from *WSHPDR 2013* to *WSHPDR 2022* by Country in Central America (MW)**



Source: WSHPDR 2022,[1] WSHPDR 2013,[2] WSHPDR 2016,[3] WSHPDR 2019[4]

Note: For SHP up to 10 MW except in the case of Mexico, where the up to 30 MW definition is used, and Guatemala, where the local definition is used.

Climate Change and Small Hydropower

The region experiences increased winter precipitation and decreased summer precipitation during the El Niño Southern Oscillation (ENSO) phase. These seasonal differences are expected to become even more pronounced as a result of climate change. The increase in frequency and intensity of extreme events on exposes SHP infrastructure to damage as well as decreases SHP plant load factors due to persistent drought.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

In **Belize**, there are no outstanding plans for any further expansions to existing SHP capacity and no incentives or funding are provided for SHP development. This lack of interest is partially informed by the increasing volatility of hydropower generation as a result of rainfall variability induced by climate change, as well as by observed negative impacts of hydropower on the environment. However, given the positive impact of international funding on the development of other RES in the country, similar support could be attracted to develop the country's remaining SHP potential.

Barriers to the development of SHP in **Costa Rica** include environmental restrictions, seasonality of river flow, competitive advantages of solar power and wind power projects, and low electricity demand. The key enabling factor for future development is the country's massive estimated SHP potential. Additionally, Costa Rica possesses considerable technical capacity in the SHP sector and a well-established framework for the development of RES projects.

SHP development in **El Salvador** is hampered by outdated hydrological data and assessments of SHP potential, as well as insufficient financing, competition from other RES due to relatively high development costs, uncertainties in the licensing process and social opposition. At the same time, the estimated SHP potential of the country is considerable and well-documented, although more up-to-date studies are needed.

In **Guatemala**, SHP development has faced opposition for social and environmental reasons, forcing the Government to develop a special consultation framework to address these concerns. Even when SHP development is not opposed by local communities, there are often problems with acquiring funding for SHP projects, particularly in light of the costs of construction and transmission in remote areas. On the other hand, SHP development in the country is facilitated by supportive government policy and by an established system for licensing and regulating SHP projects.

Barriers to SHP development in **Honduras** include issues with road access and transmission of electricity, as well as greater interest on the part of private investors in large power plants. Enablers include the highly liberalized electricity market that simplifies entry for new companies, high demand for electricity access in the countryside and abundant undeveloped SHP potential.

SHP development in **Mexico** faces a wide range of regulatory, financial, technical and political obstacles, including a lack of feed-in tariffs (FITs), rising cost of transmission, a difficult licensing process and a negative public perception of SHP. Lack of accurate nationwide data on SHP potential is another major barrier to development, although detailed partial inventories of potential sites have been developed. Despite a lack of rigorous data, the country's SHP potential is believed to be very considerable and could be more fully realized with the aid of existing incentives such as tax breaks. Additionally, the SHP sector in Mexico is well-positioned to take advantage of rising electricity demand and attractive regional electricity export prices. Finally, Mexico is a major hydropower producer and SHP developers can lean on considerable local technical expertise and construction capacities.

The main barriers to SHP development in **Nicaragua** are financial in nature and include the high upfront cost of projects, the short duration of power purchase agreements, which discourages investors, as well as subsidies for thermal power plants, which put SHP at a competitive disadvantage. Additionally, there is insufficient local technical capacity in the SHP sector. However, the country has few restrictions on foreign direct investment in the energy sector and government policy is strongly supportive of RES development, providing a range of fiscal incentives. The need to extend electricity access to certain rural areas is an additional enabler of SHP development in Nicaragua.

The most important barrier to SHP development in **Panama** is the lack of interest from private finance, meaning that SHP projects, particularly those initiated in rural communities, are dependent on state financing. At the same time, the established legal framework and system of incentives are highly supportive of SHP development, and the country has considerable experience in hydropower as well as significant untapped SHP potential. Furthermore, several ongoing SHP projects in the country have stalled and may be looking to solicit additional investments.

Belize

Areli Sutherland and Geon Hanson, Energy Unit of Belize

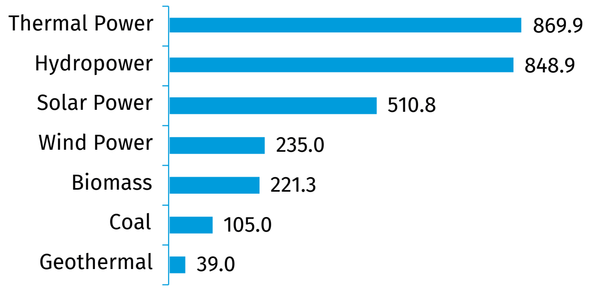
KEY FACTS

Population	397,621 (2020)[1]
Area	22,965 km^2 [2]
Topography	The topography of Belize consists of lowlands and swamps along its northern coast and the Maya Mountains in the southern part of the country. The highest point in Belize is Doyle's Delight at 1,124 metres above sea level.[2]
Climate	The climate of Belize is classified as subtropical. It is characterized by a dry season lasting from late February to May and a wet season lasting from June to November. Average temperatures in Belize City range from 23 °C in December to 29 °C in July.[2]
Climate Change	Belize is considered one of the countries at greatest risk from climate change, ranking third among small countries in susceptibility to natural disasters and fifth in climate change risk. This vulnerability is most significant with regard to hurricane damage from wind, storm surges and other flooding due to the country's coastal position and low elevation of large parts of the country. Projected changes in climate include an increase in temperatures of 2–4 °C by 2100, a 6–8 per cent increase in the length of the dry season with a corresponding shortening of the rainy season and a 20 per cent increase in the intensity of heavy rainfall events.[3,4]
Rain Pattern	The rainy season lasts from June to November, and the dry season is from February to May. Average precipitation depends on the region. In the south, annual rainfall can reach over 4,000 mm, while in the north it can be less than 1,800 mm.[2]
Hydrology	Belize has 18 major rivers in addition to many smaller perennial streams. The Belize River is the largest, running from the Maya Mountains and its tributaries in Guatemala to the Caribbean Sea for a total length of 290 kilometres and draining approximately a quarter of the country's area. Other major rivers include the Sibun River in the south and the New River in the north.[5]

ELECTRICITY SECTOR OVERVIEW

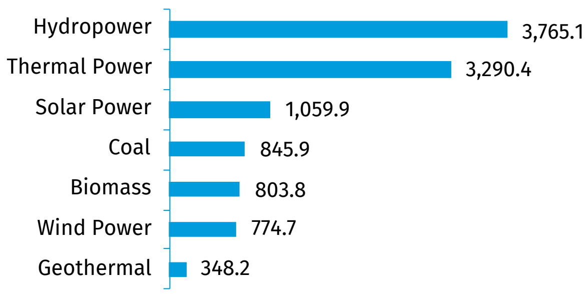
The total installed capacity of existing power plants in Belize was approximately 131.7 MW in 2020. Thermal power from fossil fuels providing 55.3 MW (42 per cent) of the total, hydropower provided 54.5 MW (41 per cent), biomass provided 21.5 MW (16 per cent) and utility-scale solar power provided an estimated 0.5 MW (less than 1 per cent) (Figure 1). In addition, approximately 3 MW of distributed solar power generation is estimated to exist in the country, but data on specific installations is not available.[6,7,8]

Figure 1. **Installed Electricity Capacity by Source in Belize in 2020 (MW)**



Source: Personn,[6] Energy Unit[7,8]

Figure 2. **Annual Electricity Generation by Source in Belize in 2020 (GWh)**

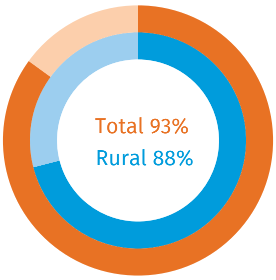


Source: Energy Unit[7,10]

Electricity generation in Belize amounted to 433.2 GWh in 2020, with the share of renewable energy sources (RES) including hydropower reaching 90 per cent. Hydropower provided 242.1 GWh (56 per cent) of the total generation, biomass provided 149.5 GWh (35 per cent), thermal power from fossil fuels provided 41.0 GWh (9 per cent) and solar power provided 0.6 GWh (less than 1 per cent) (Figure 2). The relative contribution of the different sources to the electricity supply changed dramatically from 2019, when hydropower provided only 74.7 GWh, while thermal power from fossil fuels provided 137.2 GWh. Major fluctuations in hydropower generation occurred throughout 2018-2020 due to changing hydrological conditions, requiring increasing imports from Mexico as well as generation from thermal power during certain periods. Imports of electricity from Mexico in 2020 amounted to 270.2 GWh, decreasing from 383.7 GWh in 2019.[7,9,10]

Consumption of electricity in Belize in 2020 was 539.3 GWh, representing a decline of over 8 per cent from the 2019 total consumption of 588.4 GWh. Consumption was dominated by the residential and commercial sectors at 245.3 GWh and 249.8 GWh, respectively, with industry and street lighting accounting for the remaining 44.1 GWh.[7,9,10] Overall electricity access in the country was estimated at 93 per cent in 2019, without taking into account consumers connected to off-grid generation sources.[11] Such off-grid systems are known to exist but have not yet been accurately documented. Rural access to electricity in 2019 was estimated at 88 per cent (Figure 3).[12]

Figure 3. **Electrification Rate in Belize in 2019 (%)**



Source: World Bank[12]

As the national utility, Belize Electricity Limited (BEL) is one of the largest single stakeholders in the energy sector of Belize and the only entity in the country with the legal mandate for transmission and distribution of electricity. In addition to owning and operating most grid infrastructure, BEL is a major power producer, operating the Westlake Sub Gas Turbine power plant, the Caye Caulker diesel power and mobile generators with a combined installed capacity of 32.5 MW.[6,7] As of 2020, generation contractors supplying electricity to the BEL national grid system included Santander Sugar Energy Limited (SSEL) and Belize Cogeneration Energy Ltd. (BELCOGEN) using bagasse, Blair Athol Power Company Ltd. (BAPCOL) using heavy fuel oil and Hydro Maya Limited. These entities are regulated by the Public Utilities Commission (PUC). Other independent power producers include the Belize Electric Company Limited (BECOL), which operates hydropower plants, as well as a number of small-self generators like the Farmers Light Plant Corporation in the Spanish Lookout Mennonite Community and the University of Belize solar power plant, which do not currently fall under the PUC regulatory umbrella and are regulated by other national government bodies.[8]

Since its commissioning in 2001, the PUC has been the regulatory body responsible for the electricity, water and telecommunication sectors in Belize. The PUC aims to hold the utilities to a high standard by providing high-quality services at a reasonable cost to consumers. The Directorate of Electricity within the PUC was formed by the Government in order to focus on the regulation of all entities that are licensed under the Belize Electricity Act (2000). Major activities undertaken by the Directorate include: annual review of tariffs and full tariff review every four years for the BEL; licence compliance audits; and reliability and efficiency review for licences held by BEL as well as those issued to field technicians hired by BEL. The purpose of license review is to ensure service quality and consistency within the relatively small Belize energy sector, as a supply deficit from even one power provider could have serious ramifications for electricity access in the country.[13]

Another key stakeholder in the electricity sector is the Ministry of Public Utilities, Energy and Logistics, which oversees the Energy Unit of Belize. The role of the Energy Unit comprises the development of policies, strategic direction and plans for the national energy sector as well as oversight of all matters related to energy and the country's public utilities.

All major load centres across Belize are connected to BEL's national grid system. BEL operates a transmission line backbone consisting of 115 kV and 69 kV lines, running in a north-south direction across the country and interconnected with the Mexican national electricity grid in the north. The 115 kV transmission line covers the entire northern and western zone of Belize, while the southern half of the country is fed via the 69 kV transmission line and 34.5 kV circuits feed the 115 kV backbone to transport electricity to Corozal, Orange Walk and San Pedro. Currently, Caye Caulker and the Spanish Lookout community remain as isolated load centres supplied with electricity by off-grid thermal power plants running on diesel and crude oil.[7]

Table 1. **Electricity Tariffs in Belize**

Category	*Tariff (USD/kWh)*	*Demand charge (USD)*	*Minimum/service charge (USD)*
Social	0.110	N/A	2.50
Residential	0.165–0.215	N/A	5.00
Commercial 1	0.165–0.215	N/A	5.00
Commercial 2	0.190–0.205	N/A	75.00
Industrial 1	0.150	17.91	125.0
Industrial 2	0.130	11.50	125.0
Street lights	0.225	N/A	N/A

Source: BEL[14]

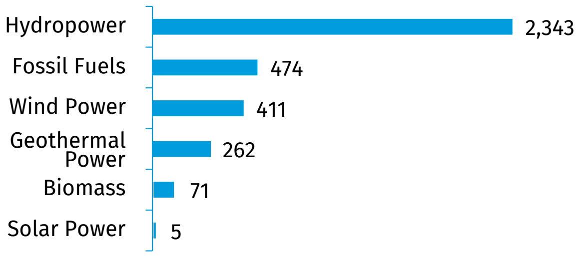
Note: Tariffs valid for the period July 2021–June 2024.

Electricity tariffs for final consumers include a minimum charge and a block charge based on consumption volume for social, residential and commercial consumers and charges based on demand and consumption for industrial consumers. Rates valid for the period from 1 July 2021 to 30 June 2024 are displayed in Table 1.

SMALL HYDROPOWER SECTOR OVERVIEW

There is no national definition of small hydropower (SHP) in Belize. Under the up to 10 MW definition of SHP, there were just two SHP plants in the country as of 2020, with a total installed capacity of 10.3 MW.[7] Additional undeveloped potential capacity is estimated at 11.4 MW, indicating that 48 per cent of the country's SHP potential has been developed so far.[15] Neither installed nor estimated potential capacity have changed relative to the World Small Hydropower Development Report (WSHPDR) 2019 (Figure 4).[16] Existing SHP plants in Belize are listed in Table 2.

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Belize (MW)**



Source: Energy Unit,[7] PÖYRY,[15] WSHPDR 2019,[16] WSHPDR 2013,[17] WSHPDR 2016[18]

Table 2. **List of Existing Small Hydropower Plants in Belize**

Name	*Location*	*Capacity (MW)*	*Generation in 2019 (GWh)*	*Generation in 2020 (GWh)*	*Plant type*	*Operator*	*Launch year*
Chalillo	Maya Mountains, Western Belize	7.0	6.86	29.03	Reservoir	BECOL	2005
Hydro Maya	Southern Belize	3.3	9.96	13.48	Run-of-river	Hydro Maya Ltd.	2003

Source: Energy Unit[7,9,10]

The most recent study of the hydropower potential in Belize was carried out in 2006. The study identified a number of promising sites for hydropower development, including sites on the Macal River and its tributaries with potential capacities of between 2.0 MW and 8.4 MW, a 1 MW site on the Privassion River and potential low-head sites along the Mopan River with a total maximum potential capacity of 15–20 MW.[15] Additional potential hydropower sites have been identified near Chiquibul as well as on the Monkey River and South Stann Creek, but no reliable estimates of potential capacity are available.[16]

RENEWABLE ENERGY POLICY

Renewable energy development targets are outlined in the Energy Policy of Belize as well as in the Nationally Determined Contribution (NDC) under the United Nations Framework Convention on Climate Change (UNFCCC), last updated in 2021. The NDC established the goal of cutting 44 kilotons of CO_2 emissions annually and the target of a 75 per cent share of RES in the national electricity supply by 2030. These targets are to be met in part through an expansion of RES capacities, including an additional 19 MW of installed hydropower capacity.[4]

In 2019, a Consolidated Project Plan (CPP) was developed and published as a collaboration between national stakeholders and the Caribbean Center for Renewable Energy and Energy Efficiency (CCREEE). The CPP provides a consolidated framework for streamlining policy targets and utility goals and incorporates RES targets established under the earlier versions of the NDC. The CPP represents a tool for further planning pertaining to both energy efficiency and renewable energy as well as for identifying opportunities within the electricity sector that offer significant economic, social and environmental benefits for the citizens of Belize.

Additional steps supporting the diversification of the energy mix of Belize and the development of hydropower in particular included the 2013 Request for Proposals (RFP) to secure adequate electricity generation or supply capacity to satisfy electricity demand in the country for the next 15 years at least cost, to be submitted through a competitive bidding process. The issued RFP targeted not only the addition of new generation capacities from RES, but also the gradual replacement of high-cost thermal generation with RES generation where possible.[19] However, no new SHP capacity was added under the 2013 RFP, and no new RFPs are being planned as of 2022.[8]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

The only in-country programme that could be considered as a financial mechanism available for SHP development is a loan initiative from the Development Finance Corporation (DFC) targeted towards homeowners and businesses for the promotion of RES in the private sector. The scope of the financing available through this scheme with regard to utility- or grid-scale plants is limited.[8]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

In both 2018 and 2019, Belize experienced an intensified dry season resulting in severe droughts, which damaged the agricultural sector and reduced the supply of electricity from hydropower as well as from biomass-fired power plants. These conditions necessitated a greater dependence on imports of electricity from Mexico, which directly corresponded to an increase in the cost of power for grid consumers in Belize.[20]

BECOL, in adjusting to the increasing volatility of hydropower generation, is developing plans to diversify its feed to the grid by adding utility-scale solar power systems to its generation mix. Generally, the effect of climate change on generation from RES is marked and will require careful planning to sustainably pursue further development.[8]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

In summary, while Belize possesses both operational SHP plants and potential for further SHP development, there are currently no defined plans in place to further develop the SHP sector, largely due to natural challenges and lack of incentives and investment.

Some barriers to SHP development in the country are:

- Increasing volatility of rainfall and hydropower potential due to climate change effects;
- Some negative environmental impacts have been observed, including elevated levels of metals in river fish, that are attributed to hydropower in general rather than specifically to SHP;
- No plans other than the NDC goals are currently in place to expand SHP;
- No financial incentives, allotted funds or large-scale investments are readily available for SHP projects.

Enablers for SHP development in Belize include:

- More than half of the identified SHP potential in the country is still undeveloped;
- The hydropower potential is recognized in the NDCs and other government policies;
- The hydropower and SHP technology is mature and already in use in the country;
- International funding and loans could be pursued to supply financial resources for SHP, as precedents exist for other RES.

Costa Rica

Marco Antonio Jiménez Chaves, Costa Rica Electricity Institute; Laura Lizano Ramón, Energy Sector Planning Secretariat, Ministry of Environment and Energy

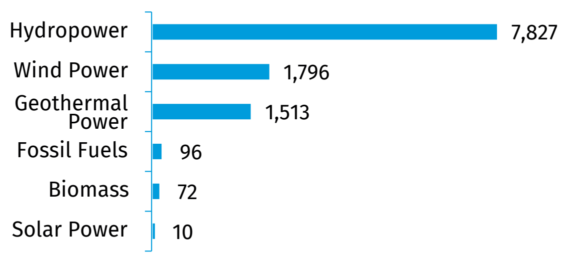
KEY FACTS

Population	5,111,238 (2020)[1]
Area	51,100 km^2 [1]
Topography	The topography is irregular, with valleys, mountain ranges and plains. Three main mountain ranges run in the longest direction, from north-west to south-east, descending towards the coastal plains and dividing the country into two slopes — the Pacific and the Caribbean. In the north-west, the Guanacaste and Tilarán Volcanic Mountain Ranges have the lowest peaks. In the centre of the country, the Central Volcanic Mountain Range forms the Central Valley. It is the most urbanized area in the country, where the capital city, San Jose, is located. The Talamanca Mountain Range lies in the south-east, with the highest peaks. Mount Chirripó is the highest mountain in Costa Rica with an elevation of 3,819 metres.[2]
Climate	Costa Rica lies within the tropical zone, between the Tropics of Cancer and Capricorn. The tropical climate is influenced by the topographic, oceanic, isthmus location and general atmospheric circulation factors. The average annual temperature is 25 °C. The country is divided into three general climate regions. The Tropical Caribbean Wet Region with monthly mean extreme temperatures between 22 °C and 31 °C. The Central Intermontane Region, with monthly mean extreme temperatures between 13 °C and 27 °C. The Tropical Pacific Region with monthly mean extreme temperatures between 23 °C and 33 °C.[3,4]
Climate Change	Climate change scenarios forecast increased rainfall south of the Caribbean and Pacific regions. Decreased rainfall is expected north of the Pacific and Central regions.[3,4]
Rain Pattern	Annual average accumulated rainfall is 3,297 mm. Different rain patterns occur in the Caribbean and the Pacific slopes. The Caribbean slope is wetter, without a defined dry season, with heavy rainfalls occurring in December and lower rainfalls occurring in February, March, September and October. Annual average accumulated rainfall in the Caribbean highlands reaches values as high as 8,000 mm. The Pacific slope is drier, with defined wet and dry seasons. The former extends between December and March; the latter extends between May and October. April and November are transitional periods. The Northern Pacific is the driest zone with annual average rainfall as low as 1,400 mm in the lowlands.[2]
Hydrology	The territory is divided into 34 main watersheds: 18 in the Caribbean slope and 16 in the Pacific slope. The largest is the Grande de Térraba watershed in the Southern Pacific, with an area of 5,085 km^2. Mean annual river flow in the territory is 70 litres per second (lps) per km^2 of watershed area. The Caribbean and Southern Pacific river flows are as high as 180 lps per km^2 of watershed area. The Grande de Térraba River has the highest mean annual flow, with 340 m^3 per second. The Northern Pacific river flows are lower than 30 lps per km^2 of watershed area.[2]

ELECTRICITY SECTOR OVERVIEW

Electricity generation in Costa Rica in 2019 reached 11,313 GWh, with 99 per cent coming from renewable energy sources, mainly hydropower (Figure 1). Seasonal variation of electricity consumption is minor, slightly higher in the dry season. Domestic electricity demand in 2019 was 11,334 GWh. Net imports within the Regional Electric Market (MER) with Central-American countries fulfilled 21 GWh for domestic electricity demand. The installed capacity in 2019 was 3,566 MW (Figure 2).[5]

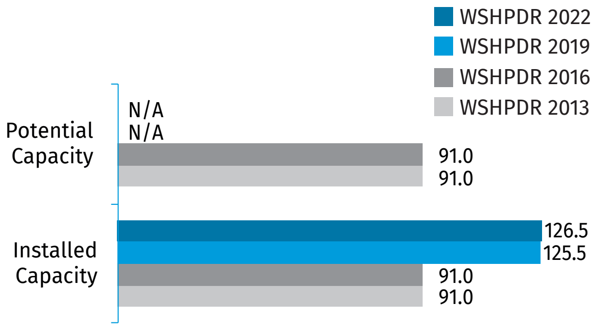
Figure 1. **Annual Electricity Generation by Source in Costa Rica in 2019 (GWh)**



Source: ICE[5]

The share of renewable energy sources in the National Electrical System (SEN) of Costa Rica is highly influenced by hydropower seasonality. During the rainy season, hydropower resources are plenty and SEN run-of-river hydropower plants spill surplus river flows. However, in the dry season hydropower resources are scarce, as a result, run-of-river production decreases significantly and hydropower generation depends on large-scale storage hydropower plants. Energy demand is then fulfilled by geothermal power or other renewable sources whose availability increases precisely in this season. Wind power and sugar cane bagasse biomass as well as endorsement from fossil fuel thermal power plants are required in a minor proportion.

Figure 2. **Installed Capacity by Source in Costa Rica in 2019 (MW)**



Source: ICE[5]

National electrification rate in 2019 was 99.4 per cent of total occupied dwellings.[6] Electricity demand grew by 1.9 per cent in 2019 compared to 2018.[5] The Energy Transition Index Report 2019 ranked the performance of the energy system of Costa Rica among the top 10 countries worldwide.[7] The public company, Costa Rica Electricity Institute (ICE), guarantees the electricity supply needed for the country's development, as mandated by Law 449.[8] ICE produces most of the electricity in the country, manages the transmission system and most of the distribution lines. Furthermore, the company is responsible for the planning and overall operation of the SEN. In 2019, ICE generated the biggest share of total electricity supply, accounting for almost 64 per cent. The share of public services distribution companies stood at 12 per cent. The private sector generation contributed 24 per cent.

Transmission lines extend widely, between the borders with Nicaragua and Panama and the Caribbean and Pacific coasts, totalling 1,725 km for 230 kV lines and 654 km for 138 kV lines. The Central American Electric Interconnection System (SIEPAC), which was completed in 2014, is the backbone of MER, which is operated by Ente Operador Regional (ORG).[9] In 2019, energy transactions within MER reached 3,074 GWh, the highest transaction volume since the establishment of MER.[10]

The main power production zone in the country is in the Northern Pacific, with hydropower plants located on rivers flowing towards the Caribbean, wind farms, geothermal fields, biomass and solar power plants.[11] The Central Valley is the main consumption zone. Distribution lines are managed by eight public services distribution companies, including ICE.[12] In 2017, an overload in the SIEPAC transmission line on the Panama side caused the most recent outage in Costa Rica. Before 2017, SEN had accomplished 10 years of service without outages.[13]

The long-term planning for the SEN is defined by ICE, in its Electric Generation Expansion Plans. For the 2018–2035 period, electricity demand is estimated to increase annually by 1.8–2.4 per cent. Capacity additions will be based entirely on renewable energy technologies.[12]

Electricity prices in Costa Rica are regulated, with no subsidies. The Public Services Regulatory Authority (ARESEP) defines methodologies for setting the tariffs. Prices differ according to the public services distribution company and the sector. The electricity prices in Costa Rica experience strong variations between the wet and dry season. The lowest annual average electricity price in 2020 was 0.09 USD/kWh for the commercial and services sector with consumption above 3,000 kWh. The highest annual average price was 0.27 USD/kWh for the industrial sector with consumption below 3,000 kWh.[14]

SMALL HYDROPOWER SECTOR OVERVIEW

There is no official local definition for small hydropower (SHP) in Costa Rica. Law 7200 defines that the private sector and cooperative companies can produce autonomous energy with limited capacity power plants (LCP) defined as hydropower or non-conventional plants with capacity up to 20 MW.[9]

In 2020, there were 37 SHP plants (up to 10 MW) in operation in Costa Rica, with a combined installed capacity of 113.3 MW. The total installed capacity of SHP up to 10 MW in the country was 126.5 MW, including four inactive SHP plants or plants with an unknown status, increasing from 125.5 MW in 2018. The 2020 investigation for the current edition of the World Small Hydropower Development Report (WSHPDR) found that no decommissioning or construction of new SHP plants was held since the previous edition (Table 1). The minor changes in installed capacity are due to a new data review (Figure 3).[5,15]

The majority of SHP plants in the country are connected to the grid. Off-grid SHP plants with a capacity of 1–10 kW are used for self-supply or in remote national parks, providing electricity support for the Ministry of Environment and Energy (MINAE) environmental protection tasks, for instance in the Cocos Island and Mount Chirripó National Parks. Public services distribution companies and private owners hold most of the operational SHP capacity, 64 per cent and 31 per cent, respectively, while ICE holds 5 per cent. The National Lighting Company (CNFL), which is the Central Valley public services distribution company and an ICE subsidiary, owns most of the oldest SHP plants in the country. Some of these plants date back to the early 20th century and, thus, require refurbishment.[16]

The investigation for the current Report found that in 2020 there were 50 limited capacity hydropower plants (up to 20 MW) in operation with a combined capacity of 328.7 MW. The total installed capacity of SHP up to 20 MW was 353.2 MW, including five inactive and unknown status plants, increasing from 352 MW in 2018.[15,16] The minor changes in installed capacity since the WSHPDR 2019 are due to a data review.

No official local estimate of SHP potential exists for the country. ICE reports 7,651 MW as the total identified hydropower potential capacity, regardless of the plant size. In this Report, the identified hydropower potential regardless of plant size is assumed as the technical potential. Installed capacity accounts for 30 per cent of the estimated technical hydropower potential. Nearly 35 per cent of the undeveloped hydropower potential is concentrated in indigenous territories and 20 per cent in national parks and reserve forest.[12]

Similar to the WSHPDR 2019, the theoretical SHP potential capacity data come from the systematic high-resolution assessment of worldwide hydropower potential by capacity.[19] Total theoretical SHP potential capacity of Costa Rica is 7,373.5 MW, which is 28.9 per cent of the country's total theoretical hydropower potential capacity, regardless of plant size, totalling 25,535.9 MW.[19] The estimated value coincides with the total theoretical hydropower potential capacity, reported by ICE.[12]

The 2018–2034 Electric Generation Expansion Plan considered the addition of three private SHP plants totalling 19 MW for SEN in 2021.[12] However, due to environmental disputes, the projects were not executed.[20] In the last years, some municipal councils are becoming increasingly concerned about the environmental impact of hydropower and have even signed moratoriums on hydropower developments in their territories, including SHP.[21] The central Government has also signed a moratorium on hydropower development in high potential watersheds.[22]

SMALL HYDROPOWER PROJECTS AVAILABLE FOR INVESTMENT

The 2020 investigation for the current Report found 52 MW of SHP projects in the feasibility stage: 33 MW from public distribution service companies and 19 MW from private SHP projects with environmental disputes as stated before (Table 2). Private SHP project capital expenditure (CAPEX) ranges between 3,500 USD/kW and 3,800 USD/kW.[12] Two other potential SHP projects for future development are Rio Piedras and PAAM, which are part of other short-term water use infrastructure plans. The Rio Piedras project consists of a 7 MW powerhouse at the toe of a 40-metre-high dam that creates a 70 hm^3 reservoir. The civil works are part of the Rio Piedras Multipurpose Project, a water storage project for crops irrigation and water supply in the Northern Pacific region.[23] The PAAM project consists of a 2.6 MW powerhouse installed in a new water supply pipe, for the Fifth Expansion Stage of the Metropolitan Water Supply System (PAAM).

RENEWABLE ENERGY POLICY

At the international level, Costa Rica has committed to the Paris Agreement and in 2020 updated its Nationally Determined Contributions (NDC), with higher ambitions for 2030. Costa Rica has also committed to adopt integrated climate actions, including mitigation and adaptation for 2030. Moreover, the country seeks to achieve the 2030 Agenda for Sustainable Development, with actions leading to increase the share of renewable energy in the overall energy mix, ensure energy access and increase energy efficiency (Sustainable Development Goal 7).

The national renewable energy policies of Costa Rica are defined in the National Energy Plans, under the guidelines of the National Development Plan established by the Government. The main objective of the current VII National Energy Plan 2015–2030 is to achieve energy sustainability with low carbon emissions. The Plan contains short-, medium- and long-term goals, with defined time limits and responsible institutions.[24] The VII National Energy Plan 2015–2030 was updated in 2019, considering new policies, regulations and plans for the energy sector. These include the Organization for Economic Co-operation and Development (OECD) accession recommendations, National Decarbonization Plan 2018–2050, National Development and Public Investment Plan 2019–2022, Law 9518 on Incentives and Promotion for Electric Transportation, National Electric Transportation Plan 2018–2030, energy sector audits, current guidelines and stakeholders' proposals.[25]

The National Decarbonization Plan 2018–2050, launched in 2019, states a net zero emissions economy goal for 2050.[26] This plan outlines the way of transforming the economy of Costa Rica towards a development model based on bioeconomy, green growth, inclusion and the improvement of the quality of life of the citizens. For the energy sector, this means electrification of the transport and industrial sectors, which is expected to cause an increased electricity demand to be met via a resilient and low-cost electricity system.

In compliance with the National Energy Plan, ICE creates Electric Generation Expansion Plans. ICE planning for the electricity sector focuses on the pursuit of sustainable development, ensuring low use of fossil fuels, diversifying renewable energy sources, fomenting MER and lowering the cost of electricity. Planned capacity investments for the 2018–2035 period include mostly renewable sources, adding up to 653 MW: 286 MW from wind power projects, 165 MW from geothermal power, 155 MW from solar power and 47 MW from hydropower, including 19 MW from private SHP projects currently discarded due to environmental disputes. The main changes from previous Electric Generation Expansion Plans are due to the downward trend of electricity demand.[12]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

In 1990, Law 7200 authorized autonomous or parallel generation, defined as electricity produced from private and public cooperative companies with LCP plants, defined as hydropower plants or plants based on non-conventional sources with lower than 20 MW capacity. Fossil fuel thermal plants, coal or large-scale hydropower are defined as conventional sources, whose development is planned by ICE according to Law 449 and national energy policies. Law 7200 regulates Build-Own-Operate (BOO) contracts signed between ICE and local or foreign private investors, which include power purchase agreements (PPA) for a period of 20 years. BOO contracts are capped to 15 per cent of total electricity production.[9] Law 7508 increased the cap of private generation by an additional 15 per cent in 1995, through Build-Operate-Transfer (BOT) contracts. Similar to BOO contracts, BOT contracts include power purchase agreement (PPA) for 20 years.[27] As stated by Law 7200, ICE buys electricity from BOO and BOT contracts, according to the ARESEP tailored tariffs for these plants. The size of power plants is regulated by Law 7200: 20 MW maximum capacity under BOO contracts and 50 MW maximum capacity under BOT contracts with local and foreign private investors.[5,28]

The licensing process for BOO contracts is defined in Law 7200. ICE calls for LCP bids in compliance with the Electric Generation Expansion Plan. Private investors interested in hydropower LCP development submit eligibility applications. Licensing approval requires an ICE declaration of eligibility, a granted concession from the Water Department of the Ministry of Energy, a granted concession from ARESEP and the National Technical Environmental Secretariat (SETENA) declaration of an Environmental Viability Licence. An Environmental Viability Licence is granted following a staged procedure. Depending on the impact evaluation required in each stage of the process, the projects advance to further stages requiring more details on the environmental impacts and countermeasures. Existing and old plants are subjected to the same process.[29]

For BOT contracts ICE also calls for bids in compliance with the Electric Generation Expansion Plan. BOT contracts are assigned through public bidding with price competition and technical, economic and financial capacity evaluations of the bidders.[9] In 2003, Law 8345 authorized public services distribution companies to use available energy sources in the country for meeting the electricity demand in their coverage areas. The licensing process for public services distribution companies is defined by Law 8345. The main requirements are a granted concession from the MINAE Water and Energy Departments for projects with less than 60 MW of capacity and a SETENA declaration of an Environmental Viability Licence.[30]

Since the global financial crisis in 2008, the electricity demand has demonstrated a downward trend, mainly due to economic factors. Several projects already defined between 2008 and 2015 were commissioned, leading to a surplus capacity that can support the country's electricity demand up to 2026, according to the Electric Generation Expansion Plan. Directive No. 68-MINAE for the energy sector was published in August 2020 to prevent electricity costs from rising. According to this Directive, the Ministry of Energy would not grant concessions or environmental permits for any type of new power projects for a one-year period to avoid an excessive installation of generating capacities, which could result in increased service costs.[31]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

In Costa Rica, SHP projects financing has been made by public and private commercial banks, national and international, as well as through trust funds. For projects regulated under Law 7200, loans above maximum credit limits for commercial banks can be authorized by the Central Bank of Costa Rica (BCCR). Tax exemption applies to imported machinery, waterway equipment and all equipment required for electricity generation.[9] For projects regulated by Law 8345, loans exceeding USD 10 million per year can be authorized by BCCR. The same tax exemptions apply to Law 7200.[28] Moreover, several SHP plants were also financed by the Kyoto Protocol Clean Development Mechanism (CDM). Furthermore, Costa Rica participates in the Guacamaya SHP project funded under the CDM.[32]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The Inter-American Development Bank (IADB) published in 2016 a study about growing hydropower vulnerability in Central America due to climate change. The study focused on climate change effects for the seven main hydropower plants of the region, one for each country. Based on the climate change models of the Intergovernmental Panel on Climate Change (IPCC) and the projected changes in inflows, the study forecasted for the 305 MW Reventazón hydropower plant in Costa Rica a 2.3 per cent increase in generation in 2030 and a 13.9 per cent decrease in generation in 2090. The corresponding economic impact is estimated to be between USD 22 million and USD 244 million.[33]

Similarly, local preliminary studies indicate that climate change (i.e., increased rainfall south of the Caribbean and Pacific Regions or decreased rainfall in the north of the Pacific and Central Regions) could generate losses for SEN of between USD 200 million and USD 314 million yearly. Generation by fossil fuel thermal plants could reach 15 per cent of total electricity generation in 2080 if the country does not harness local renewable energy sources.[34] The natural inflow energy from the SEN hydropower sources turned out to be the lowest in 2019, taking into consideration all available water inflow data since 1965.

Costa Rica has not defined any official adaptation measures for the SHP sector. However, for large-scale hydropower, ICE focuses on sediment management, to preserve reservoir capacities in the long term.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Nowadays, the SHP sector in Costa Rica represents 5 per cent of installed hydropower capacity and is mainly owned by private and public service distribution companies. In the last decades, SHP has constantly contributed to the electricity sector of the country. However, the future development of SHP is expected to encounter more limitations than in the past. According to the authors, the main barriers for future SHP development in Costa Rica are:

- Environmental: The municipal and Government moratoriums on hydropower development in high-potential watersheds were put in place due to environmental concerns of the impact of SHP.
- Run-of-river seasonality: Currently, the share of renewable energy in the energy mix is highly influenced by the hydropower generation pattern. SHP plants are mainly run-of-river, thus, producing surplus electricity in the rainy season and providing less electricity in the dry season. Therefore, diversification of the energy mix is required for providing renewable electricity during the low season of hydropower generation.
- The improved competitiveness of solar and wind power projects: Solar and wind power projects have seen their CAPEX plummet dramatically in the last decade. Additions of these resources may reduce the operational marginal costs of SEN during the low season of hydropower generation, thus reducing the overall operating expenses (OPEX) of the SEN.
- Downward trend of the electricity demand: Electricity demand has been very low in the last years in Costa Rica. The existing installed capacity is enough for meeting the demand for the next years, therefore, there will be no need for new projects until 2026. To prevent electricity costs from rising, Directive No. 68-MINAE, published in August 2020, dictates that MINAE must not give concessions, nor environmental permits for any type of new power projects for a one-year period.

According to the authors, the main enablers for future SHP developments are:

- Technical know-how: Through the installed hydropower capacity and over 60 years of its existence, the sector accumulated strong experience with high-skilled staff, companies and all the necessary features for future environmentally sustainable and cost-effective hydropower development.
- SHP potential: There is a significant untapped potential for the development of SHP projects, which represents a sustainable way to harness the untapped hydropower potential in the country.
- Renewable energy policies: Energy policies encourage the development of renewable energy projects. Environmental and cost-competitive SHP projects (e.g.,

projects that can take advantage of existing and/or multipurpose planned facilities) may be interesting to fulfil the renewable energy share.

El Salvador

Juan José García Méndez and Victor Sagastume, National Council of Energy

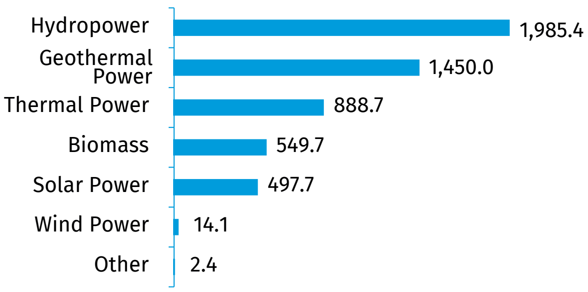
KEY FACTS

Population	6,704,864 (2019)[1]
Area	21,040.8 km² [1]
Topography	The topography of El Salvador is dominated by parallel mountain ranges stretching from east to west and separated by a central plateau, which together comprise 85 per cent of the territory of the country. A narrow coastal plain extending to the Pacific Ocean accounts for the remaining 15 per cent. The highest point in El Salvador is Santa Ana in the southern mountains, at 2,365 metres above sea level.[2]
Climate	The climate in El Salvador is tropical and is characterized by two seasons — a dry season from November to April and a rainy season from May to October. The annual average temperature is estimated at 26 °C. During summer, temperature usually varies between 26 °C and 30 °C, while in winter it only drops to approximately 21 °C to 24 °C.[3]
Climate Change	Climate change models predict a rise in temperatures of 1.5–2.0 °C by 2040–2050 and of 2.5–4.5 °C by 2091–2100, relative to the 1961–1990 baseline period. The eastern parts of the country are expected to experience the most significant increases in temperature. Rainfall is expected to decrease by as much as 20–35 per cent by the end of the century.[4]
Rain Pattern	Average annual precipitation in El Salvador is 1,865 mm and can reach 2,000 mm in certain mountainous parts of the country. The variation in rainfall between the driest and the wettest months is approximately 227 mm.[2,3]
Hydrology	El Salvador has 11 hydrographic regions that are delimited by the basins of the country's main rivers. One of the most important is the Lempa River region, with an area of 10,082 km², which represents approximately 48 per cent of the national territory.[5]

ELECTRICITY SECTOR OVERVIEW

The total installed electricity capacity of El Salvador was 2,360.2 MW in 2020. Thermal power from fossil fuels provided 771.1 MW (33 per cent) of the total, hydropower provided 573.8 MW (24 per cent), solar power provided 474.5 MW (20 per cent), biomass provided 293.6 MW (12 per cent), geothermal power provided 204.4 MW (9 per cent), wind power provided 36.0 MW (2 per cent) and biogas provided 6.9 MW (less than 1 per cent) (Figure 1).[6]

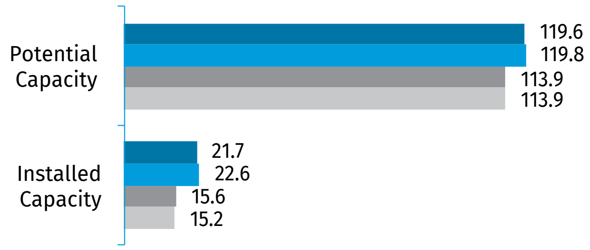
Figure 1. **Installed Electricity Capacity by Source in El Salvador in 2020 (MW)**



Source: SIGET[6]

Generation of electricity in 2020 amounted to 5,387.9 GWh. Hydropower contributed 1,985.4 GWh (37 per cent) of the total, geothermal power contributed 1,450.0 GWh (27 per cent), thermal power from fossil fuels contributed 888.7 GWh (16 per cent), biomass contributed 549.7 GWh (10 per cent), solar power contributed 497.7 GWh (9 per cent), wind power contributed 14.1 GWh (less than 1 per cent), and other sources contributed an additional 2.4 GWh (less than 1 per cent) (Figure 2). Total electricity generation increased by nearly 4 per cent relative to 2019. Generation from solar power increased nearly 130 per cent, while generation from fossil fuels decreased by approximately 45 per cent.[6] Approximately 85 per cent of electricity generation in 2020 was provided by renewable energy sources (RES), but this figure varies from year to year due to differences in weather, particularly in rainfall. The gap between generation from biomass and installed capacity of biomass-fired power plants is explained by the fact that biomass (bagasse) fuel is sourced from sugar cane and the plants operate only during the sugar cane harvest season between November and April rather than year-round.

Figure 2. **Annual Electricity Generation by Source in El Salvador in 2020 (GWh)**



Source: SIGET[6]

The electricity grid of El Salvador is composed of the high-voltage transmission network (above 115 kV) and the mid/low-voltage distribution network (below 115 kV). The transmission network in 2020 consisted of 41 115 kV lines with a total length of 1,073 kilometres, 24 substations and four 230 kV lines that interconnect the transmission system of El Salvador with that of Guatemala (14.6 kilometres) and Honduras (92.9 kilometres). The distribution of electricity is carried out by eight different companies supplying energy at different voltages. The overall length of the distribution lines is over 48,000 kilometres and the system supplied electricity to 1,907,939 end users as of the end of 2020.[6]

Access to electricity in El Salvador in 2020 was nearly 98 per cent nationwide, 99 per cent in urban areas and 95 per cent in rural areas.[7] Efforts have been started to develop a master electrification plan to provide technically and economically feasible solutions for communities still lacking electricity access. Electricity consumption in 2020 was 5,915.9 GWh, decreasing from 6,361 GWh in 2019 due to the impact of the COVID-19 pandemic, while peak demand reached 1,010 MW. Transmission losses accounted for 1.8 per cent of total electricity supply. Electricity imports covered the gap between domestic generation and total electricity demand and reached 642.6 GWh in 2020, decreasing by 50 per cent relative to 2019.[6]

The electricity market of El Salvador is composed of the wholesale electricity market and the retail electricity market. The wholesale market is constituted by the Long-Term Contracts Market (CLP) and the Spot Market (MRS). In order to participate in it, the installed capacity of a power plant must be at least 5 MW and it can be connected to either the transmission or distribution network. To participate in the retail electricity market, the installed capacity of the power plant must be less than 20 MW and it can only be connected to the distribution network. Bilateral contracts can be signed in both markets (power purchase agreement), to commercialize the electricity generated.[8]

El Salvador is additionally part of the Regional Electricity Market (MER), which operates under the Framework Treaty of the Central American Electricity Market, approved by Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua and Panama in May 2000. Its general design conceptualizes the MER as a seventh market. The six existing country markets or national systems have agents authorized by the Regional Operator Entity (EOR) and carrying out international electric power transactions in the Central American region.[9] All member countries are interconnected through the Central American Electrical Interconnection System (SIEPAC) transmission network.

Historically, as in many other countries in Latin America, the energy sector in El Salvador was first developed by the state. The electricity market was vertically integrated, with the activities of generation, transmission, distribution, commercialization and long-term planning of the energy sector being controlled and regulated by the state. Due to several policies implemented by the Government in the 1990s, the electricity market, among others, underwent reforms of laws and regulatory frameworks. As a result of these reforms, the electricity market became open to private investment and therefore changed to a competitive market. Its growth and development were driven by demand, which resulted in the state losing its role in the planning and strategic development of the sector.[9]

The first component of this reform was the approval of the Law of Creation of the General Superintendence of Electricity and Telecommunications (SIGET) and the General Law of Electricity. Both laws were approved by the Congress in 1996. The role of regulator of the electricity and telecommunications market was given to SIGET.[9]

The second component consisted of dissolving the state companies that operated the electricity sector. The activities of power generation, transmission, distribution, commercialization and operation of the electricity system were privatized. The National Council of Energy (CNE) was created in 2007, in an attempt to reinstate the strategic planning role of the state. CNE started operations in 2009 and established the National Energy Policy 2010–2024.[9] Aiming to accelerate the energy transition in El Salvador, in 2021 the CNE presented the new National Energy Policy 2020–2050, which includes the following strategic goals: regulatory modernization; sustainable energy supply; efficient energy consumption; research, development and innovation; and energy security and integration.[10]

The CNE is constituted by the ministers or vice-ministers of the government departments related to the different aspects of the energy sector's development, including the Ministry of Economy, the Technical Secretariat of the Presidency, the Ministry of Treasury, the Ministry of Public Works, the Ministry of Environment and Natural Resources and the Consumer Protection Agency.[9]

In addition to the CNE, the electricity sector is composed of the following agents:

- Electricity generating companies;
- The transmission agent (ETESAL), a private company responsible for the planning of the expansion, construction of new extensions and maintenance of the national transmission network;

- Private electricity distribution companies operating the low-voltage distribution networks;
- Electricity traders, private or public agents that perform selling and buying transactions in the domestic and regional electricity market to meet the demands of any other agent, including final users;
- The Transaction Unit (UT), an independent market and system operator in charge of operating the transmission system, maintaining the security of the system, ensuring a defined minimum quality of the services and supplies and also operating the wholesale electric power market;
- The SIGET is the regulatory entity responsible for applying the laws and regulations that govern the electricity and telecommunications sectors in the country.

The end user's electricity bill in El Salvador includes three charges: an energy charge, distribution charge and marketing charge. The energy charge is approximately 80 per cent of the bill and is adjusted quarterly based on Article 90 of the General Electricity Law Regulations. The adjustments are made on 15 January, 15 April, 15 July and 15 October of each year. The average unsubsidized prices of the electricity tariff to end users for the first semester of 2020 are presented in Table 1. The electricity subsidy applies to residential users with a monthly consumption of 1–105 kWh, for a value of USD 5.00 per month. For industrial consumers, the energy charge is calculated based on power level and not on consumption.

Table 1. **Electricity Tariffs in El Salvador in 2020**

Tariff category	*Semiannual average price (USD/kWh)*
Low voltage:	
Total residential average	0.2018
General use	0.1773
Public lighting	0.1636
Medium demand (10–50 kW)	0.2234
High demand (> 50 kW)	0.2015
Medium voltage:	
Medium demand (10–50 kW)	0.1617
High demand (> 50 kW)	0.1442
Overall average price of distributors	0.1721

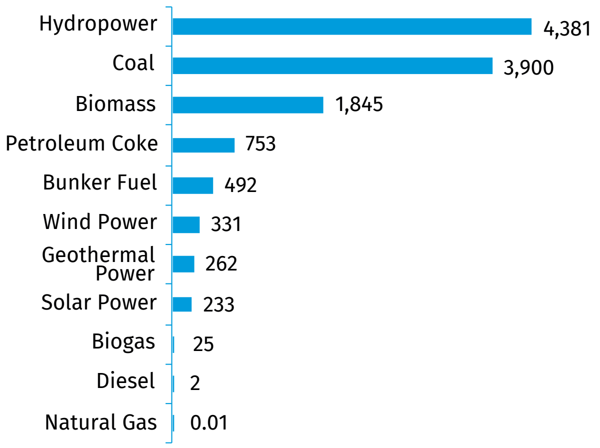
SMALL HYDROPOWER SECTOR OVERVIEW

The definition of small hydropower (SHP) in El Salvador is a hydropower plant with an installed capacity off less than or equal to 5 MW.[11] The total installed capacity of SHP up to 5 MW in El Salvador was 21.7 MW in 2020; however, there are no SHP plants in the 5–10 MW range in the country, so the installed capacity for SHP up to 10 MW is the same. In addition, there are two non-operational plants with a combined capacity of 0.625 MW.[12] The potential undeveloped capacity for SHP up to 10 MW has been estimated at 97.3 MW by previous publications and for SHP up to 20 MW at 157.6 MW.[12,13,14] The total SHP potential up to 10 MW, including existing operational and non-operational plants and undeveloped potential, can therefore be estimated at 119.6 MW. Relative to the World Small Hydropower Development Report (WSHPDR) 2019, the installed capacity of SHP plants up to 10 MW decreased by approximately 4 per cent, while the estimate of potential capacity decreased by less than 1 per cent, in both cases due to a reassessment of the installed capacities and operational status of several existing plants (Figure 3).[13]

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in El Salvador (MW)**



Source: García Méndez & Sagastume,[12] WSHPDR 2019,[13] JICA,[14] WSHPDR 2013,[15] WSHPDR 2016[16]

Note: Data are for SHP up to 10 MW.

A list of existing operational SHP plants in El Salvador is provided in Table 2. The current status of two previously operational plants, the 600 kW Atehuasías SHP plant and the 25 kW La Chacara SHP plant, is unclear, but they are likely inactive and in need of rehabilitation.[12] Two ongoing SHP projects on the San Simón River are listed in Table 3, while a list of several potential SHP sites available for investment is displayed in Table 4.

RENEWABLE ENERGY POLICY

One of the strategic guidelines of the National Energy Policy 2010–2024 (NEP) is the diversification of the energy mix and the promotion of renewable energy resources. Since the implementation of the NEP, several adjustments have been made in the legal and regulatory frameworks of the electricity and environmental sectors as well as to taxation regulations to foster the development of renewable energy generation projects. The most significant adjustments include the following:

- The Law of Fiscal Incentives for the Promotion of Renewable Energy in Electricity Generation. The law establishes the type and duration of the fiscal benefits granted by the state to encourage the construction of new renewable energy power plants.
- The categorization of the environmental impact of activities, works or projects in the energy sector. Its purpose is to determine if a project requires an Environmental Impact Study (EIS) before its implementation.
- The Rules of Bidding Processes for Long-Term Contracts Supported with Renewable Distributed Generation establish the rules to follow in the implementation of this kind of public bidding processes.
- The Standard for End Users that Generate Electricity with Renewable Resources establishes the rules to follow by the end users for installing small power generation systems for self-consumption and the retribution model for sporadic energy injections in the distribution network.[13]

COST OF SMALL HYDROPOWER DEVELOPMENT

The Japan International Development Agency estimated the cost of SHP development in El Salvador in a 2012 Master Plan study for the development of RES in the country. The study proposed a three-phase programme for realizing the potential of the 123 identified SHP sites, with costs per phase ranging between 2,761 USD/kW and 3,391 USD/kW and with an overall average cost of 2,972 USD/kW.[14]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

El Salvador has taken significant steps at the regulatory and institutional level to promote the development of hydropower plants (and RES in general). Nevertheless, structural issues that may hinder development still persist, including the following:

- Lack of accurate hydrological data;
- Outdated estimates of SHP potential;
- The period to obtain a concessions permit is not clearly defined and induces uncertainty in the development process;
- Potential social opposition to SHP projects;
- The high investment costs of SHP in El Salvador compared to competing RES technologies;
- Few domestic options for financing SHP plants.

The key enablers of SHP development in the country are:

- Several detailed studies of SHP potential and inventories of potential SHP sites in the country have been conducted, although the collected data are not up-to-date;
- Significant unrealized SHP potential remains.

Guatemala

Jonas Dobias, Water and Energy Independent Consultant

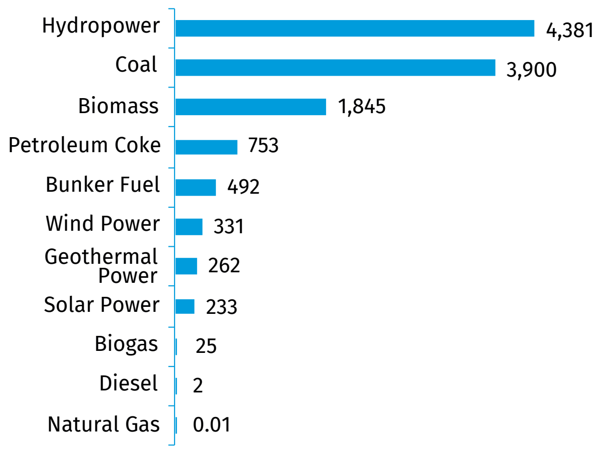
KEY FACTS

Population	16,850,000 (2020)[1]
Area	108,889 km[2] [2]
Topography	A tropical plain of approximately 48 kilometres in width parallels the Pacific Ocean. Guatemala also has a piedmont region, which rises to altitudes of 90–1,370 metres. Nearly two-thirds of the country lies above these regions, in a mountainous, volcanic area stretching from the north-west to the south-west. The highest peak is Tajumulco (4,211 metres). To the north of the volcanic belt lies the continental divide and, even further north, the Atlantic lowlands.[2]
Climate	Guatemala is divided into three climatic zones. Daytime temperatures can reach as high as 40 °C and temperatures at night rarely drop below 20 °C. At approximately 1,000–2,000 metres above sea level lies a zone with temperatures rarely exceeding 30 °C. Daytime temperatures there are only slightly lower than in the temperate zone; however, the nights are rather cold and temperatures can drop below freezing.[2]
Climate Change	Due to climate change, the temperatures are projected to increase by 2.1–4.5 °C by 2050 and by 3.3–5.4 °C by 2070. Precipitation is expected to decrease by 9.5–12.4 per cent and 18.4–28.9 per cent for the same periods.[3]
Rain Pattern	Precipitation varies across the dry (May to October) and wet (November to April) seasons. The average annual rainfall in Guatemala for the period 2001–2016 was approximately 1,967 mm.[4]
Hydrology	In terms of hydrology, the country can be divided into three main areas. The Pacific Rim comprises 18 river basins. The coast on the Caribbean Sea, which includes the most important river, the Motagua, comprises 10 basins. There are also 10 basins in the Gulf of Mexico region, home to the most abundant rivers in the country.[2]

ELECTRICITY SECTOR OVERVIEW

In 2019, total electricity generation in Guatemala was 12,224 GWh, of which 2,102 GWh were exported, mainly to the Regional Energy Market (MER), formed by Guatemala, El Salvador, Honduras, Nicaragua, Costa Rica and Panama. A small portion was exported to Mexico. At the same time, 1,068 GWh were imported from the MER and Mexico. Hydropower accounted for 4,381 GWh of total domestic generation, followed by 3,900 GWh from coal, 1,845 GWh from biomass, 753 GWh from petroleum coke, 492 GWh from bunker fuel, 262 GWh from geothermal power, 331 GWh from wind power, 233 GWh from solar power, 25 GWh from biogas, 1.66 GWh from diesel and 0.01 GWh from natural gas. Hydropower was the main source, accounting for approximately 36 per cent of the generation in 2019 (Figure 1).[6]

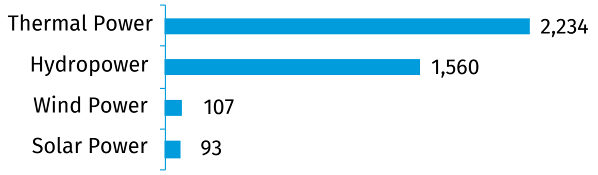
Figure 1. **Annual Electricity Generation by Source in Guatemala in 2019 (GWh)**



Source: AMM[6]

In 2019, the total installed capacity of Guatemala was 3,993 MW and available capacity stood at 3,415 MW. Of the total installed capacity, combustion (coal, diesel, bunker fuel and biomass) accounted for 56 per cent, hydropower for 39 per cent, wind power for 3 per cent from and solar power for 2 per cent (Figure 2).[6]

Figure 2. **Installed Electricity Capacity by Source in Guatemala in 2019 (MW)**



Source: AMM[6]

The total electrification rate in the country in 2019 was above 92 per cent.[6] However, there is a big gap between the more urban departments and the departments with high rural population. Guatemala is divided into 22 regions and each region, in its turn, is divided into municipalities, with a total of 340 municipalities in the country. Fourteen regions have an electricity network coverage of above 95 per cent; four of approximately 90 per cent; two of between 80 per cent and 85 per cent; one of approximately 68 per cent and one of 44 per cent.[7] The lowest electrification rate is recorded in the northern area, where the lowest economic indicators are shown.

Since 1998, the electricity sector in Guatemala works as an open market, where the Wholesale Market Administrator (AMM) has two products for transactions: electric power (MW) and electricity (MWh). There are two procedures for these transactions. The first one is based on prices fixed in mid- and long-term contracts; this is where most of the transactions are completed. The second one is executed through the AMM, where the transactions are based on costs set by the Regulation of the Wholesale Market Administrator (RAMM) rather than on market prices.[5] Electricity generating companies set their own electricity costs and the AMM calls them for dispatching in an order from the lowest to the highest cost on the spot market.

The electricity sector in Guatemala is unbundled, involving both state and private players, known as electricity market agents, who are active in the generation, transmission, trading and distribution segments. The electricity sector planning in Guatemala is overseen by the Ministry of Energy and Mines (MEM), while the National Electricity Commission (CNEE) is in charge of regulation. Energy dispatching is operated by the non-governmental organization AMM.

The state-owned company INDE owns 14 per cent of the total installed capacity, mainly hydropower, while the other 86 per cent is owned by the private sector. In total, there are eight transmission companies. The largest one is operated and owned by INDE (over 75 per cent of the total), while the other seven are privately-owned, of which one owns the regional line of SIEPAC. There are 19 distribution companies. One belongs to INDE and provides services to 42 per cent of users, two private companies provide services to 51 per cent of users and 16 municipal companies provide services to the remaining 7 per cent of users.[8]

The electricity tariffs in Guatemala are set by the CNEE every five years. These are adjusted every three months based on the electricity bought by the distributor, cost of electricity transmission and the distribution taxes (Table 1). In general, the price of electricity depends on the exchange rate the US dollar, international fuel prices and current hydrological conditions. Households that consume less than 300 kWh per month receive a subsidy from the state through INDE. A street light service cost is added to every user according to the municipality tariffs.

Table 1. **Electricity tariffs in Guatemala, May–July 2020**

Company	*Social tariff (USD/kWh)*	*Regular tariff (USD/kWh)*
DEOCSA	0.23	0.25
DEORSA	0.22	0.23
EEGSA	0.16	0.17

Source: CNEE[9]

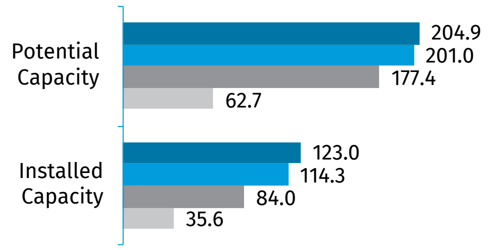
The Government plans to develop the electricity sector are enclosed in the following documents:

- The National Energy Plan 2017–2032, which is based on three axes: (i) sustainable use of natural resources; (ii) energy efficiency; and (iii) greenhouse gas emissions reduction.
- The Expansion Plan for the Generation and Transportation System 2018–2032, which, according to the RAMM Article 15, should cover a period of 10 years and be updated every 2 years.
- The Energy Policy 2019–2050, which is based on five axes: (i) electricity supply and use; (ii) fuel supply and use; (iii) energy efficiency; (iv) firewood use; and (v) sustainable development.
- The Expansion Plan for the Generation System 2020–2050, whose objectives are: (i) promotion of investments in electricity generation from renewable sources; (ii) promotion of natural gas, solar and wind power; (iii) focus on a strategic power system resilient to climate change; (iv) promotion of generation systems in areas where they do not currently exist; (v) integration of new energy sources into the transmission system. This plan also sets the objective to install approximately 60 power plants, from which seven are small hydropower (SHP) plants. The plan has also set three scenarios of annual electricity demand for 2050: low at 18,940 GWh, medium at 25,345 GWh and high at 42,510 GWh.
- The Rural Electrification Plan 2020–2050, which sets seven indicators for the selection of potential areas for rural electrification, the majority of which are off-grid. The plan also states an estimated investment cost for the implementation in each area.[10,11,12,13,14]

SMALL HYDROPOWER SECTOR OVERVIEW

In Guatemala, the definition of SHP refers to plants that have an installed capacity below 5 MW. In total, there are 74 SHP plants registered as a distributed renewable generator with MEM. Sixty-five plants are currently operating (123 MW), 33 are registered but are not operating (80 MW) and one is pending registration (1.9 MW). In comparison to the World Small Hydropower Development Report (WSHPDR) 2019, four new SHP plants have been commissioned with a combined capacity of 5.1 MW (Figure 3, Table 2). These started operating by the end of 2018 and the beginning of 2019.[14]

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Guatemala (MW)**



Source: WSHPDR 2016,[2] MEM,[15] WSHPDR 2013,[16] WSHPDR 2019[17]

Note: Data are for SHP up to 5 MW.

There is currently no accurate estimate of the SHP potential capacity in Guatemala. During the 1970s and 1980s, a Master Hydropower Plan for the country was developed, which estimated hydropower capacity at approximately 5,000–6,000 MW.[18] However, this capacity is only theoretical. Based on the combined capacities of operating, registered and pending-registration SHP plants, it can be assumed that there is at least 204.9 MW of SHP potential.

Most SHP projects in Guatemala are developed privately or through development assistance from international donors. The list of planned SHP projects to be connected to the national grid is shown in Table 3.

San Francisco	Quetzaltenango	0.40

Source: AMM[19]

There are micro-hydropower plants (below 1 MW) not connected to the national grid, which are generally located in remote rural areas and are directly operated by small local communities. Normally, these micro-hydropower plants have been funded by international cooperation programmes, which own their distribution grids that are not connected to the national grid. In addition, some municipalities have their own plants. Most, if not all, of them are old and out of service due to lack of maintenance. In some cases, they are damaged due to natural catastrophes, such as floods, resulting from hydrological extreme events. Although there are no concrete plans, some of these already have a prefeasibility study.

SMALL HYDROPOWER PROJECTS AVAILABLE FOR INVESTMENT

There is no official list of selected SHP sites available for development. However, the author of this chapter, as a technical adviser and hydrologist for MEM and CNEE, was responsible for the technical evaluation of three municipal hydropower plants that are currently out of service (Table 4).

RENEWABLE ENERGY POLICY

The sustainable use of renewable energy resources is included in the first axis of the National Energy Plan for 2017–2032, the Guatemalan Climate Change Framework Law and the National Policy on Climate Change.[10,21,22] Furthermore, the promotion of investment into renewable energy technologies and of a strategic power system resilient to climate change are specific objectives included in the Expansion Plan for the Generation System 2020–2050.[13] The Plan also includes the construction of 60 hydropower plants, of which 6 are SHP plants. The aforementioned plans also align with international agreements, such as the United Nation Framework Convention on Climate Change (UNFCCC), the Paris Agreement and the Nationally Determined Contributions (NDCs). Concerning the latter, Guatemala has committed to an 11.2 per cent reduction of its carbon emissions by 2030 (or 22.6 per cent provided it can count on the technical and economic assistance from international donors). This reduction is focused on five sectors for mitigation actions, including the energy and transport sectors.[23]

Furthermore, the Rural Electrification Plan 2020–2050 has set the objective of reaching a 93.5 per cent electrification rate by 2023. The plan also describes the potential use of micro-hydropower plants (5–100 kW) and micro-grids in remote areas.[14]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

There are no specific government plans or programmes targeting SHP. However, the National Energy Plan 2020–2050 and the Expansion Plan for the Generation System 2020–2050 call for the implementation of small and micro-hydropower plants of up to 5 MW and 1 MW of capacity, respectively. Furthermore, the Technical Norm for Generation of Renewable Energy and Self-Producers with Energy Excess (NTGDR) is another example of regulations focusing on small-scale renewable energy plants (up to 5 MW). The NTGDR describes that SHP and other renewable energy plants can sell their electricity to the national electricity market or sell directly to the distribution companies.[24]

The development of hydropower below 5 MW does not make use of the national grid. Therefore, such projects do not require an authorization from MEM. However, they must be registered with MEM, as established in Article 8 of the General Electricity Law.[25] Such projects must be completed with several requirements, such as an Environmental Impact Assessment or an Environmental Flow Design from the Ministry of Environment and Natural Resources (MARN) to obtain the Environmental Licence. They also have to fulfil other requirements from different institutions, including the localization and forestry management documentation from the National Committee for Protected Areas (CONAP) and the National Institute for Forestry (INAB), respectively, as well as connection authorizations or studies from CNEE, AMM and INDE.

Overall, SHP development in the country is facilitated by a developed system of institutions responsible for registering, granting licences and conducting connection studies for SHP development projects are:

- MEM, responsible for the registration of SHP projects, national and official publication of renewable energy regulations, including tax incentives for renewable energy projects. MEM is currently developing a model for hydropower development, which requires developers to comply and align with the International Labour Organization (ILO)'s "C169, Indigenous and Tribal Peoples Convention";
- CNEE, responsible for the authorization of connection to the main electric grid;
- AMM, responsible for the required study to be incorporated in the energy wholesale market;
- INAB, responsible for the certification for forestry management;
- CONAP, responsible for the certification stating that the project is not developed in a protected area;
- MARN, responsible for environmental impact assessments.

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

INDE is one of the biggest financial sources for the implementation of rural electrification projects. At the moment of writing of this chapter, INDE was evaluating the possibility to receive a loan of USD 100 million from the Inter-American Development Bank (IDB) to finance and execute the Rural Electrification Plan 2020–2050.[14] Another mechanism aimed to promote the development of renewable energy in the country is the Law on Incentives for Renewable Energy Development, which exempts equipment and machinery used for renewable energy projects from custom tariffs. The law also provides tax exemptions during the first 10 years of operation of such projects.[26]

In previous years, the programme called Green Micro, Small and Medium Enterprises (MIPYMES Verde) used to be the main financial mechanism for the development of SHP in the country. The programme concluded in 2017. However, a second phase is planned to promote the development of renewable energy projects (solar power, hydropower, wind power, biomass and biogas) under 5 MW of installed capacity, for which a reimbursable fund of approximately USD 40 million is available. Nevertheless, as of 2021, due to the COVID-19, the status of the programme remained uncertain.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Currently, Guatemala has not established any climate change adaptation measures for SHP plants in its regulation. However, projects may establish their own adaptation measures.

During a workshop on climate change and its effects on hydropower generation organized by CNEE in 2014, four national experts on hydrology for hydropower were invited to discuss the threats that climate change presents to hydropower development. They also discussed the potential options to minimize the negative impacts. One of the conclusions was that, considering the expected increases in temperatures and decreases in precipitation, the estimated potential of hydropower in the country (5,000–6,000 MW) may be lower in the near future. Furthermore, it was also concluded that an increase in the density of the grid of hydrological and climatic gauges in the country is needed.[18]

Furthermore, the IDB and the Latin American Organization for Energy (OLADE) developed a study called "Vulnerability of the Hydropower System due to Climate Change in Central America and Adaption Options". The study analyzed one main hydropower plant in each country and concluded that, despite climate change being a menace in the region, hydropower will still be a viable option for energy supply in the region. However, it recommended that new projects should consider the variability of the climate in the short, mid and long term.[27]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Some barriers to the development of SHP and hydropower in general in Guatemala are:

- Environmental and social opposition to the development of hydropower. For this reason, the MEM has developed a methodology for consulting local populations based on the ILO Convention C169;
- In some cases, the hydropower potential is located far from the main grid (distribution or transmission lines) and connection lines turn out to be very expensive relative to the whole hydropower project;
- Economic and financial limitations, particularly for off-grid hydropower in rural communities, where international cooperation and assistance is the main funding source.[28]

The key enablers for further SHP development in the country include:

- A developed system of institutions responsible for registering, granting licences and conducting connection studies for SHP projects;
- Available undeveloped potential;
- Government policy conducive to renewable energy development.

Honduras

Laura Stamm, International Center on Small Hydro Power (ICSHP)

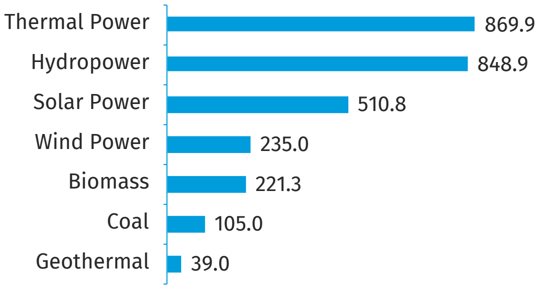
KEY FACTS

Population	9,904,608 (2020)[1]
Area	112,491 km^2 [2]
Topography	The Central American Cordillera Mountain Range sweeps the country east to west so that more than 75 per cent of the country's surface area is mountainous. The highest altitudes are found in the western region, where the country's highest point, Cerro Las Minas at 2,870 metres, is situated. The Volcanic Highlands are to the south-west. Very narrow plains can be found along the southern coast of the Gulf of Fonseca that opens to the Pacific Ocean. The northern coast with the Caribbean Sea has slightly wider plains, particularly in the north-eastern lowland region known as La Mosquitia.[3,4]
Climate	The climate in Honduras is temperate in the interior mountain areas and tropical near the coasts. Average temperatures in the highlands are between 19 °C and 23 °C with the highest areas being cooler, at approximately 14°C. Average temperatures in the coastal lowlands are between 26 °C and 28 °C, but are usually higher between May and November. The Caribbean coast remains hot and humid throughout the whole year, but the Pacific coast has a dry period between December and April when temperatures can be slightly cooler.[3]
Climate Change	In the past 50 years, average temperatures in Honduras have increased by approximately 0.4 °C and extreme weather events have also considerably increased. In 2015, German Watch's climate risk index classified Honduras as the country most affected by extreme weather events caused by climate change during the 1994–2013 period. These trends are expected to continue, specifically regarding the prevalence of hurricanes experienced by the country. Average temperatures are expected to rise by between 2.1 °C and 4.6 °C by the end of the century, with the interior highland region being most susceptible to the highest increase. A decrease in average rainfall is also anticipated.[5]
Rain Pattern	The rainy season throughout the country is generally from May to November. The northern coastal region experiences the most rainfall, between 1,800 mm and 2,800 mm annually. While rainfall happens all year long in this area, the heaviest rainfall and occasional hurricanes happen between June and November. Average rainfall in the southern coastal region is between 1,500 mm and 2,000 mm per year, almost all of which happens between May and November. Average rainfall in the interior mountain regions is between 1,000 mm and 1,800 mm annually.[3]
Hydrology	Honduras is a water-rich country. The majority of the waterways flow from the interior mountains to the north, emptying into the Caribbean. There are 14 significant rivers that produce approximately 82 per cent of the country's runoff that follows this path. The most important rivers that flow northwards are the Ulúa, Patuca and Aguán. These rivers often flood for a portion of the year and are at their lowest points between March and May. In the south, there are five rivers that flow from the interior and empty into the Pacific, and the Goascorán River is the most important of them. The rivers Lempa and Coco are considered border rivers, forming the borders with El Salvador and Nicaragua, respectively. The largest lake in the country is Lake Yojoa with an area of approximately 90 km^2, located within the western highlands.[6]

ELECTRICITY SECTOR OVERVIEW

At the end of 2021, total installed capacity in Honduras was approximately 2,830 MW, more than 65 per cent of which was renewable energy. Installed capacity of thermal power, mostly heavy fuel oil, was just under 870 MW (31 per cent). Hydropower accounted for approximately 849 MW (30 per cent), solar power for slightly less than 511 MW (18 per cent), wind power for 235 MW (8 per cent), biomass for just above 221 MW (8 per cent), coal for 105 MW (4 per cent) and geothermal power for 39 MW (1 per cent) (Figure 1).[7] There are three state-owned thermal power plants which comprise a combined 30 MW of installed capacity and six state-owned hydropower plants amounting to 537 MW. The remaining 2,263 MW of installed capacity is dispersed between numerous privately-owned plants. The largest single power plant is the state-owned Francisco Morazán hydropower plant with 300 MW of installed capacity.[7]

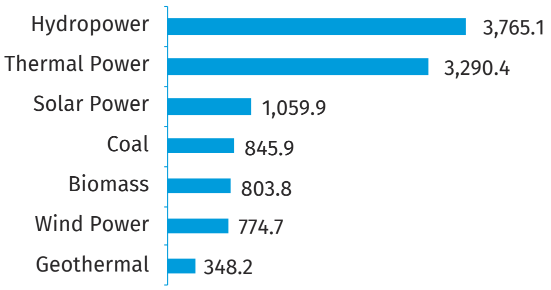
Figure 1. **Electricity Installed Capacity by Source in Honduras in 2021 (MW)**



Source: ENEE[7]

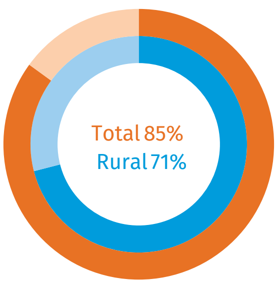
The total electricity generated in Honduras in 2021 was 10,888 GWh. Hydropower accounted for 3,765 GWh (35 per cent), thermal power generated 3,290 GWh (30 per cent), solar power 1,060 GWh (10 per cent), coal 846 GWh (8 per cent), biomass 804 GWh (7 per cent), wind power 775 GWh (7 per cent) and geothermal power 348 (3 per cent) (Figure 2). An additional 204 GWh was imported, most of which came from Guatemala.[7]

Figure 2. **Annual Electricity Generation by Source in Honduras in 2021 (GWh)**



Source: ENEE[7]

Figure 3. **Electrification Rate in Honduras in 2019 (%)**



Source: Government of Honduras[8]

There is a considerable number of isolated rural communities throughout Honduras, particularly in the east, and many lack infrastructure connecting them to the more populous and urban epicentres in the west. This results in a contrast of electrification rates throughout the country. The overall electrification rate in 2019 was 85 per cent, with a 95 per cent urban electrification rate and 71 per cent in rural areas (Figure 3). Connection varies greatly throughout the rural areas, as the department of Gracias a Dios in the far north-eastern Mosquitia region has the lowest electrification rate of the country with less than 8 per cent.The state-owned National Company of Electrical Energy (ENEE) was originally created in 1957 in order to assume full responsibility of all the generation, distribution and transmission of electricity in the country. However, in the early 1990s, electricity demand grew at a faster rate than the ENEE could supply, which resulted in the passing of the Electricity Subsector Framework Law of 1994 which opened the sector for private companies to sell energy to ENEE. The law also created the National Commission of Electric Energy (CNEE) to oversee the contracts between ENEE and private companies. In 2014 full liberalization of the electricity sector emerged with the General Law of the Electric Industry, with the goal to improve efficiency through decentralization. Subsequently, the Regulatory Commission for Electric Energy (CREE) was established as a regulatory authority in the newly liberalized market. The Ministry of Natural Resources and the Environment (SERNA) grants environmental licences and oversees the sector as a whole.[8]

Electricity tariffs are set by CREE based on such factors as currency fluctuation, fuel prices and the state of the generation, transmission and distribution subsectors. Tariffs vary according to the type of consumer and usage and in January of 2022 prices per kWh ranged from USD 0.16 to USD 0.25.[9]

SMALL HYDROPOWER SECTOR OVERVIEW

Small hydropower (SHP) is defined in Honduras as hydropower plants with a capacity of up to 30 MW. In December of 2021, there were 45 SHP plants up to 30 MW with a combined installed capacity of 288.6 MW. Of these SHP plants, 37 had a capacity of up to 10 MW with a combined capacity of approximately 148 MW.[3] The total hydropower potential in Honduras is approximately 5,000 MW and the SHP potential up to 10 MW is estimated to be 385 MW (Table 1).[10] In comparison with data from the World Small Hydropower Development Report (WSHPDR) 2019, the installed capacity has increased by 20 MW, more than 15 per cent, due to the completion of new SHP plants, while the potential remained unchanged (Figure 4).

RENEWABLE ENERGY POLICY

The first legislation that was passed with the goal to reduce the country's dependence on fossil fuels was the Law for Renewable Energy of 1998 under Decree No. 267-1998. This provided tax incentives for renewable energy generation up to 50 MW and obligated state company ENEE to purchase renewable energy at a maximum price. Tax incentives include exemption of import and sales tax and a five-year income tax exemption.[8,15] To further push for an increase in renewable energy, the Law on the Promotion of Electric Power Generation with Renewable Resources was passed in 2007. This augmented the incentives from the 1998 decree and included preferential tax and sales policies. It granted income and import taxes and dispatch priority of renewable energy on the grid.[13,16] Additional decrees in 2011 and 2013 further expanded on incentives for renewable energy. In particular, they:

- Created a registry of small renewable energy producers;
- Set transmission charges of 0.01 USD/kWh for renewable energy projects;
- Extended the incentives for renewable energy projects, such as exoneration of income tax, import duties and concession fees (except for hydropower) and tax credits on pre-investment expenditures;
- Extended the incentives to off-grid projects for distributed generation;
- Established net-metering for users under 250 kW;
- Established a special incentive for solar photovoltaics (PV) projects that had started operations before August 2015, fixing the duration of the 10 per cent incentive at 15 years and adding an extra premium of 0.03 USD/kWh. Limited to projects under 50 MW and not exceeding 300 MW of total installed capacity;
- Exonerated all renewable energy projects that provide an Environmental Impact Assessment (EIA) from construction permit fees.[13]

These initiatives are aimed at facilitating the transition of the energy mix in compliance with the provisions of the Country Vision and National Plan Law constituted into State Policy by Decree No. 286-2009. This law stated the goal to reach an energy mix composed of 60 per cent renewable energy by 2022 and 80 per cent renewable energy by 2038.[17] The goal to reach 60 per cent renewable energy has since been reached.

Rural electrification using renewable energy is a priority in Honduras. In 2012, the Honduras Scaling-Up Renewable Energy Programme in Low-Income Countries (SREP) was approved by the Inter-American Development Bank (IADB). This secured more than USD 30 million in grants and near-zero interest for a diverse programme of investment plans aimed at creating a more conducive environment for the renewable energy sector. Specific activities financed under the SREP include: a grid-connected renewable energy programme; a rural electrification strategy to accelerate electricity access in remote areas; promoting access to improved and appropriate cooking technologies; and a policy and regulatory reform initiative intended to improve the conditions for development of the country's renewable energy sector.[18] The SREP is an ongoing fund and as of 2021 was still accepting project requests. Recent activity includes a 2020 approval of the construction of 20 solar-powered mobile health units and an international bidding held in May of 2021 to supply goods and related services to constructing a mini-grid in isolated regions, including the least electrified department of the country.[19,20]

LEGISLATION ON SMALL HYDROPOWER

To develop SHP in Honduras, special licensing and permits granted by SERNA are required based on the size of the project, separated into three categories. For category 1 projects, between 0.5 MW and 1 MW, a Certificate of Environmental Registry must be obtained but has minimal requirements. Category 2 projects, between 1 MW and 3 MW, require an Environmental Authorization licence which calls for a qualitative environmental assessment amongst other requirements. Category 3 projects, above 3 MW, require an Environmental Licence and an EIA to be carried out at the site. For all projects, an additional contract of water is required.[21]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Some key barriers hindering the development of SHP in Honduras include:

- The equity capacity by private investors in Honduras is concentrated in larger, fossil fuel-based energy projects;
- The lack of road infrastructure and ancillary services markets;
- The need to invest in a transmission network.[13]

Some enablers that could encourage SHP development in the country:

- Full market liberalization allows for new entries into the market;
- Most of the total hydropower potential has not yet been utilized, leaving much opportunity;
- The low rural electrification rate in the country exhibits a need for more power plant developments, particularly in the eastern region of the country.

Mexico

Sergio Armando Trelles Jasso, Mexican Institute of Water Technology (IMTA)

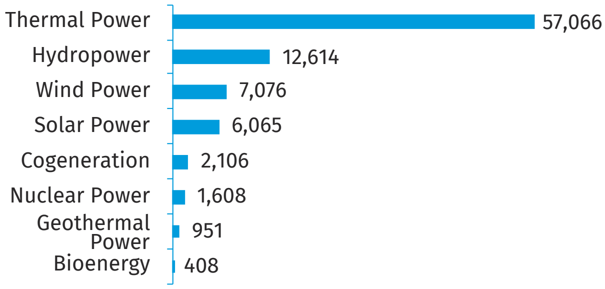
KEY FACTS

Population	126,014,024 (2020)[1]
Area	1,965,262 km^2 [2]
Topography	The relief of Mexico is characterized by several mountainous chains, including the Peninsula of Baja California (1,200 km long), Western Sierra Madre (1,400 km), Eastern Sierra Madre (600 km), Southern Sierra Madre (1,000 km), Sierra Madre of Oaxaca (300 km), Central American Mountain Range (with a peak altitude of 4,092 metres) and Neovolcanic Axis (with a peak altitude of 5,610 metres). The altitude of the Central High Plateau ranges from 500 metres to 2,600 metres. From these formations the altitude descends to the Northern Plateaus, the Sonora and Chihuahua Deserts and the coastal plains along the Pacific Ocean and the Gulf of Mexico. The Peninsula of Yucatan in the far south-east is a flat karst formation with almost no streams or rivers.[3]
Climate	The average temperatures range from 16 °C in the states of Tlaxcala and Mexico to 27 °C in the Peninsula of Yucatan.[4] The minimum temperatures, below -6 °C, occur in December and January in the northern mountainous areas. The maximum temperatures, above 48 °C, have occurred between April and July in the north-west, along the Pacific coast and the central parts of the country. There is a great diversity of climate: dry in most of the centre and north (28 per cent of the country); very dry in the north-west (21 per cent); warm and humid in the south (5 per cent); warm subhumid along the coasts (23 per cent); temperate humid in the mountains of the south (3 per cent) and temperate subhumid in the mountains near the coasts (21 per cent).[5]
Climate Change	Mexico is highly vulnerable to the effects of climate change, which impacts both human populations and ecosystems. It is expected that cyclones will be more intense in the north-west, as well as along the Pacific and Atlantic coasts. Strong storms are likely to become more frequent, increasing the risk of flooding. At the same time, most of the country is projected to become drier and drought frequency is also likely to increase, with a consequent increase in the demand for water.[6]
Rain Pattern	From 1981 to 2010, the average annual precipitation in the country was 740 mm. The spatial distribution varies greatly, from 98 mm in the Río Colorado to 2,220 mm in the Coast of Chiapas. Annual precipitation extremes range from 33 mm in the north-west to above 4,500 mm in the south-east.[7] The rainy season, from May to October, accumulates 83 per cent of the annual rainfall. Every year, between July and October, there are tropical storms and hurricanes that reach both littorals. From 1970 to 2015, there were 224 such events, most of them on the Pacific coast, but the strongest ones occurred on the Atlantic coast.[8,9]
Hydrology	The country is divided into 37 hydrologic regions, which are further divided into 158 river basins and 976 subbasins.[10] The total mean runoff is estimated at 354,990 hm^3 per year, equivalent to 180 mm per year across the entire country or approximately 21 per cent of the annual rainfall. Two thirds of the total runoff occur in seven river basins that cover 22 per cent of the surface of the country: Grijalva-Usumacinta, Papaloapan, Coatzacoalcos, Balsas, Pánuco, Santiago and Tonalá.[9]

ELECTRICITY SECTOR OVERVIEW

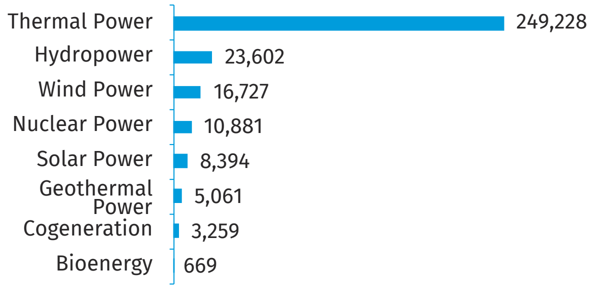
The total installed capacity of Mexico in 2020 was 87,894 MW, indicating a 12 per cent increase since 2019. Of this total, thermal power from fossil fuel sources contributed 57,066 MW (65 per cent), hydropower contributed 12,614 MW (14 per cent), wind power contributed 7,076 MW (8 per cent), solar power contributed 6,065 MW (7 per cent), efficient cogeneration contributed 2,106 MW (2 per cent), nuclear power contributed 1,608 MW (2 per cent), geothermal power contributed 951 MW (1 per cent) and bioenergy contributed 408 MW (less than 1 per cent) (Figure 1). Relative to 2019, there has been a marked increase in all forms of clean renewable energy, particularly solar power capacity, which increased by over 66 per cent. Conversely, hydropower installed capacity remained stable. The largest generating capacities are located in the states of Chiapas, Veracruz and Guerrero, while states with the smallest installed capacity include Morelos, Campeche and Mexico City.[11]

Figure 1. **Installed Electricity Capacity by Source in Mexico in 2020 (MW)**



Source: SENER[11]

Figure 2. **Annual Electricity Generation by Source in Mexico in 2019 (GWh)**



Source: SENER[11]

There are four types of entities in Mexico that produce electricity and contribute to the total installed capacity. The state-owned Federal Electricity Commission (CFE) owns a 51 per cent share of the installed capacity, operating a variety of technologies including the country's only nuclear power plant. Independent power producers that sell all their production to CFE own 19 per cent of total capacity, primarily operating combined-cycle plants and some wind power plants. Private producers that are authorized to sell electricity on the open market own 28 per cent, operating combined-cycle plants and a variety of plants based on renewable energy sources (RES). Finally, the state-owned oil company PEMEX owns approximately 1 per cent of the total capacity, operating plants based on efficient cogeneration, conventional thermal power and gas turbine technologies.[11]

The total annual electricity generation in 2019 was 317,820 GWh, with thermal power providing 249,228 GWh (over 78 per cent) of this total, hydropower providing 23,602 GWh (7 per cent), wind power providing 16,727 GWh (5 per cent), nuclear power providing 10,881 GWh (3 per cent), solar power providing 8,394 GWh (nearly 3 per cent), geothermal power providing 5,061 GWh (nearly 2 per cent), efficient cogeneration providing 3,259 GWh (1 per cent) and bioenergy providing 669 GWh (less than 1 per cent) (Figure 2). The combined share of electricity generated from clean renewable and clean non-renewable sources was nearly 22 per cent of total generation.[11] It is also notable that nearly 59 per cent of electricity generated in 2019 was provided by combined-cycle and gas turbine plants, which import 90 per cent of the gas used for generation from the United States of America (USA).[12]

The National Electric System (SEN) is organized in nine regions, each with a control centre. Seven of the regions cover most of the territory of the country with dense electric transmission and distribution networks that constitute the National Interconnected System (SIN). The remaining two regions are on the peninsula of Baja California that has three regional networks: one on the north (BCN), linked to an electrical network in the USA; another in the south of the state (BCS); and the isolated network of Mulegé (MUL).

The electricity grid infrastructure comprises the National Transmission Network (RNT), which has 55,816 kilometres of high voltage transmission lines (230–400 kV), continued by 54,497 kilometres of high voltage subtransmission lines (69–161 kV) and the General Distribution Networks (RGD), which have 872,946 kilometres of medium- and low-voltage distribution lines (from 33 to less than 2.4 kV). As of 2021, the RNT possessed a transformation capacity of 165,713 MVA, while the transformation capacity of the RGD was 77,978 MVA.[11] The technical and non-technical losses in the SEN are estimated at 12 per cent. There is a programme in execution to control losses. The expectation is to limit the losses to 8 per cent in 2034, following the international standard.[13] There are ongoing projects across Mexico to expand the RNT and RGD to meet increasing electricity demand, improve reliability, reduce costs, and fulfill clean energy goals.

On the northern border, Mexico has 11 interconnections with the states of Texas and California in the USA, with capacities ranging from 36 MW to 800 MW. On the southern border, a transmission line of 103 kilometres at 400 kV linking Mexico and Guatemala started operation in 2010.[14] There are plans to connect this strategic link to the Central American Electrical Interconnection System (SIEPAC), traversing 1,800 kilometres at 230 kV with a capacity of 600 MW and serving six countries of the Regional Electricity Market of Central America.[15] In addition, Mexico has been connected to Belize since 1998 by a transmission line of 115 kV and 230 kV with a capacity of 65 MW, which supplies approximately 70 per cent of the demand in Belize.

To connect a new power plant with capacity equal to or greater than 0.5 MW to the grid, it is necessary for the National Centre of Energy Control (CENACE) to execute one or more technical studies to ensure the reliability of the electric system. These include an Indicative study, an Impact on the System study, as well as an expedited Installations Study and Impact Study. The cost and the duration of the studies vary depending on the capacity of the plant. For example, for a small hydropower (SHP) plant of up to 30 MW, the set of studies can cost approximately USD 49,000 USD and require up to 55 working days.[16]

CFE has plans to build, acquire or participate in the development of power generation plants in order to maintain its leadership in the sector and ensure a 54 per cent share of national electricity generation by 2027 is to be met through the addition of 13 thermal projects, with an estimated investment of approximately USD 10 billion.[13]

The national electrification rate in the first quarter of 2021 was nearly 100 per cent, although a small degree of variation in electricity access exists throughout the country, with Mexico City having the highest rate of access at over 99.9 per cent.[17] Due to the operating reserve margin, shortages of electricity on a regional or seasonal scale normally do not occur. Some outages of electric supply of short duration and limited extent may occur, caused mainly by strong winds or heavy rain events.[18] However, in the last decade there have been several outages caused by major natural disasters, accidents and the strong dependence on gas imports from the USA for electricity generation. The most significant outage occurred on 15 February 2021, caused by the disruptions to gas supply infrastructure in Texas, USA as a result of extreme weather. Notably, on that occasion power was restored in Mexico much earlier than in Texas because of the rapid increase in generation by hydropower plants located in the south-eastern part of Mexico.

Electricity consumption in Mexico is highest in August and lowest in February. The overwhelming majority of electricity (nearly 95 per cent) is consumed by users connected to the SIN, mainly in the Central, Western and North-eastern regions. The remainder is accounted for by the two regional networks, BCN and BCS, in Baja California. The final consumption by end users in 2019 equalled 274,917 GWh. Medium industry accounted for 38 per cent of this total, large industry for 25 per cent, residential users for nearly 25 per cent, commercial users for 6 per cent, agriculture for nearly 5 per cent and services for nearly 2 per cent. The maximum demand of capacity in 2019 was 45,946 MW. The threshold of 95 per cent of maximum demand was exceeded in 131 of the 8,760 hours of the year, while the load factor was 76 per cent.

The Secretariat of Energy (SENER) has analyzed three scenarios (high, planning and low) of the expected growth in the capacity demand and electricity consumption for the period 2020–2034. The national gross consumption in the SEN for 2034 under an assumption of 2.7 per cent yearly increase, is expected to reach 483,317 GWh, 49 per cent higher than in 2019. Similarly, final consumption is expected to grow at a yearly rate of 3.1 per cent. The maximum demand of coincident capacity in the SEN for 2034, assuming a 2.8 per cent annual increase, is expected to reach 73,790 MW, a 60 per cent increase relative to 2019.[11]

A process of radical reforms of the legal and institutional framework of the energy sector was initiated in 2013, focusing mainly on the oil and gas industry, but also targeting the electricity sector. As part of the reforms, Articles 25, 27 and 28 of the Constitution were amended, along with 12 national laws, while 9 new laws were adopted in 2014, with a subsequent adjustment or adoption of the corresponding bylaws.[19] Changes included the partial privatization of the electricity sector. Previously, the right to generate, transmit, transform, distribute and supply electric energy for public service was exclusive of CFE. Following the reforms, the Government remained responsible for the planning and control of the SEN as well as for the RNT and RGD, while private companies were allowed to participate in the generation and sale of electricity and associated products, with the exception of nuclear power and the supply of electricity to residential consumers. The roles of the main public institutions in the electricity sector were adjusted accordingly, including those of the SENER, CFE, Regulatory Commission of Energy (CRE), CENACE, Secretariat of Environment and Natural Resources (SEMARNAT), National Water Commission (Conagua) and National Commission for the Efficient Use of Energy (CONUEE).

CFE and PEMEX, the national oil and gas company, were redefined as state-owned productive enterprises, required to compete with private companies and additionally allowed to form public-private partnerships. CFE was divided into nine subsidiary enterprises and four affiliated enterprises. The generation capacity of CFE was split among six subsidiaries that compete with each other using a variety of energy sources, including one business unit for nuclear power.

The legislative approval of the 2013 Energy Reform was extremely controversial since its inception and revealed many conflicts of interest among the political forces promoting this reform. The administration of Andrés Manuel López Obrador, inaugurated in December 2018, declared its intention to review the Energy Reform of the 2013 with the aim of moderating the most detrimental effects, rather than enact a complete reversal. A Presidential proposal to amend the Reform on a constitutional level was rejected in a historic vote on 17 April 2022. However, earlier measures to mitigate some aspects of the Reform were adopted on 9 March 2021 as part of amendments to the Law of Electric Industry, and finally validated by the Supreme Court of Mexico on 7 April 2022.[20] These measures are intended to promote the CFE as the predominant actor in the electricity sector and include the following:

- Modifications to electric dispatch criteria to prioritize hydropower and all CFE-owned plants over private plants of all other technologies;
- Obligation of all energy sector contracts to comply with the planning criteria defined by SENER;
- Issuance of Clean Energy Certificates (CEL) regardless of ownership and date of start of operation, to now include CFE's clean energy plants;
- Eliminating the obligation of CFE to buy energy for basic supply through auctions;
- Revocation of self-supply generation permits deemed to be fraudulent;
- Revision of existing Government contracts with independent power producers.[21]

The Wholesale Electricity Market (MEM) was launched in 2016 and is supervised by CENACE. The products sold on the

MEM include electric energy, capacity balance, CEL, ancillary services (SC) and financial transmission rights (DFT), among others. Within the MEM, participants have the option to conduct deals on five markets: the Short-Term Energy Market, composed of the Day-Ahead (MDA), the Real-Time (MTR) and the Hour-Ahead (Spot) markets; the annual Capacity Balance market; the CEL market, held at least annually; the periodic DFT market; and the medium- (3 years) and long-term (15–20 years) auctions of Energy, Capacity and CEL.

Interested parties, either legal entities or natural persons undertaking entrepreneurial activities, can register in the MEM as market participants under six modalities: Generator, Qualified User, Supplier of Basic Services, Supplier of Qualified Services, Supplier of Last Resort and Non-Supplier Marketer. The only supplier for residential consumers is CFE-Basic Supply. Private companies can be generators, suppliers and marketers of electricity directly to qualified users. Qualified users of energy, with demands of 1 MW or more, are able to buy from the MEM, from suppliers of qualified services or directly from generators. Private companies are allowed to participate in the expansion and operation of the transmission and distribution networks. Energy marketers and qualified users must buy a minimum percentage of capacity, either continuous or interruptible.

The MEM is an hourly cost market. The final price depends on the marginal cost of generation. The price is regulated by SENER, CENACE and CRE. The hourly Local Marginal Prices of electricity (PML) are calculated at 2,536 local price nodes of the SEN (NodoP), taking into account an energy factor, system losses and congestion of the substations. These prices are published online.[22]

CELs have been issued and traded since 2018. There have been three long-term auctions awarding 15-year contracts for the purchase of clean energy and CELs in 2016 and 2017, mainly to solar and wind power projects. The resulting average prices of electricity have decreased from 41.80 USD/MWh to 33.47 USD/MWh, and then further to a price of 20.57 USD/MWh. The decrease in prices has been associated with commercial competition and the reduction of costs of wind and solar power projects. A fourth auction was called in 2018, but later cancelled in 2019. The price scheme for the electric transmission service has been adjusted to reduce subsidies.[23]

An important amendment to the Law of the Electric Industry (LIE) promoted by the President entered into force on 10 February 2021. One of the amendment's main provisions changed the priority assigned by CENECE in dispatching the generation of power plants: first priority was assigned to hydropower plants; second, to the rest of CFE's power plants; third, to wind and solar power plants owned by private producers; last, to combined-cycle and other power plants owned by private producers. Additionally, CELs will be issued to all plants generating clean energy, including CFE's large hydropower plants. The amendment also stipulated that the Suppliers of Basic Services, including CFE, will no longer be obliged to buy products through energy auctions. Previously, the CFE had been buying electricity at auctions at prices higher than the electricity generated by its own plants, in a form of public subsidy for private producers. Finally, new technical feasibility criteria for intermittent energy sources were introduced for the connection to the grid and the legality and profitability with regard to the national budget of all permits and existing contracts relating to self-supply generators and IPPs will be reviewed and renegotiated or revoked.[24] However, this amendment precipitated strong opposition from private developers and the struggle concerning its application is ongoing.

As per Article 12 of the LIE, the CRE holds responsibility for setting the electricity tariffs in Mexico, in addition to other legal powers, including the granting and modification of generation permits, determination of rules of payment of production to distributed generators, issuance of grid and basic supply tariffs, issuance of rules and supervision of the MEM, authorization of model contracts for MEM and interconnection of power plants, granting of CELs, establishing the definition and criteria of clean energy, defining the rules for clean energy generation and for capacity acquisition, authorization of energy auctions, expression of opinion on the expansion of RNT and RGD, authorization of standards of interconnection of power plants, authorization of imports and exports of energy, record keeping of MEM participants, regulation and supervision of the standardization process and fostering the training of personnel for clean energy generation.[24]

The electricity tariff structure established by CFE takes into account the connection voltage level, the category of use, the region, the season, the required and used demand, the required continuity, the type of energy source, the day of the week and the level and hour of consumption (base, intermediate and peak). Consequently, more than 40 different tariffs are in place for different connections and usage characteristics. In general, the highest tariffs are those of the Baja California and Baja California Sur regions, while the lowest are applied in the North Central, North-eastern and North-western regions. The tariffs are charged in Mexican pesos (MXN) and are indexed on a monthly basis.

The transmission tariffs applicable to Qualified Users of the MEM for 2021 were: 76.3 MXN/MWh (3.74 USD/MWh) for connections up to 220 kV,and 173.7 MXN/MWh (8.53 USD/MWh) for connections below 220 kV.[23] The mean tariff for all users in November 2017 was 86.07 USD/MWh, assuming an exchange rate of 18.91 MXN/USD on 16 November 2017.[18] From that date, the federal Government has endeavoured not to increase the electricity tariffs at more than the official yearly inflation rate.

SMALL HYDROPOWER SECTOR OVERVIEW

There is no legal definition of SHP in Mexico. However, a hydropower plant is considered eligible for incentives aimed at promoting clean and renewable energy projects when its capacity is up to 30 MW or when it has a power density of at least 10 W/m^2, which is the ratio of installed capacity to water surface in the reservoir.[25] As of May 2019, CRE had issued 148 permits to existing hydropower plants or new projects, although six permits have subsequently been either revoked or terminated. Of the remaining 142 permits, 110 are permits for SHP plants up to 30 MW, including operational plants as well as ongoing and planned projects.[18,26]

There are 69 SHP plants in operation in Mexico with a combined capacity of 699.3 MW and an authorized annual generation of 3,193.2 GWh. Of this total, 32 belong to CFE and 37 to other private or public entities. All of the SHP plants in operation are connected to the national electric grid.[26] No official nationwide estimate of SHP capacity up to 30 MW is available. Relative to the World Small Hydropower Development Report (WSHPDR) 2019, both installed and estimated potential capacity have remained constant, as no new SHP plants have been commissioned (Figure 3).[27] A partial list of operational SHP plants in Mexico is provided in Table 2.

Source: CRE[26]

Additionally, there are 41 SHP plants under construction or waiting to start construction with a combined capacity of 452.5 MW and an authorized generation of 2,277.0 GWh. One of these plants belongs to CFE and 40 to other private or public entities.[26] A partial list of ongoing SHP projects is provided in Table 3.

Table 3. **List of Selected Ongoing Small Hydropower Projects in Mexico**

Location	*Capacity (MW)*	*Annual generation (GWh)*	*Operator*	*Planned launch year*	*Development stage*
Guerrero	30.0	150.0	Mexicana de Cobre	2013	Construction
Veracruz	26.0	118.0	Hidroeléctrica Solís	2014	Construction
Noroeste	30.0	191.7	Generadora Fénix	2016	Construction
Guerrero	30.0	146.2	Proyectos Hidroeléctricos de Puebla	2016	To start works
Puebla	27.4	108.8	Industrias Wack	2017	To start works

Source: CRE[26]

Note: Data are from 2019

For several decades, CFE has been conducting planning studies focused on identifying potential hydropower sites with an expected production greater than 40 GWh/year. In 2012, its inventory included 585 such sites, including 73 plants now in operation. The combined potential capacity of the remaining 512 sites was estimated at 41,132 MW, with a potential generation of 114,754 GWh/year and an average utilization factor of 32 per cent.[30]

In 1995, CONAE published a national estimate of SHP potential in Mexico of approximately 3,250 MW, considering plants with a capacity of between 2 MW and 10 MW.[31] However, this assessment was based on an incorrect extrapolation from data on other countries. Subsequently, the author of the original estimate stressed the urgent need to conduct a more rigorous assessment of the national SHP potential.[32] Nevertheless, up until the present day many official and academic documents have continued to cite the figure of 3,250 MW as a fact.

Subsequently, SENER has published an estimate of the total probable SHP potential of 2,700 MW, based on the aforementioned studies carried out by CFE.[33] This value was based on the combined capacity of 489 sites picked from the 512 in the CFE inventory, raising the utilization factor to 100 per cent and reducing the height of the dams. The methodology applied was of questionable quality and this estimate is largely uncertain.

Furthermore, there have been several official assessments of the SHP potential in natural streams of certain river basins, which, however, cover only a very small portion of the national territory. These studies have a widely varying degree of hydrological and topographical precision. At the low end of the precision spectrum, in 1995 a study was commissioned by CONAE of six watersheds on the coast of the Gulf of Mexico, covering 26,376 km^2, where a total of 100 SHP sites were identified using simplified techniques and data.[32] At the high end of the spectrum are the studies commissioned by CFE in 2007 for three watersheds, covering 29,259 km^2, where a total of 3,118 micro-, mini- and small hydropower sites were identified through applying a more advanced methodology.[34]

Taking into account the rugged relief and heavy rainfall patterns across the many river basins of Mexico which have not yet been studied, it can be assumed with high confidence that once a systematic and exhaustive assessment of the SHP theoretical, technical, economic and environmental potential is carried out, thousands of feasible sites will be identified, and that the total potential capacity will be considerably larger than the partial estimates available up to this point. A quick analysis of conditions for SHP development in Mexico reveals that, assuming a proportional hydropower potential with China and the EU, there could be between 9,800 and 11,500 viable hydropower plants in Mexico, with the majority being SHP plants. However, Mexico had only 100 plants of all sizes in operation as of 2019.[35,36]

The benefits that hydropower can offer the population of Mexico in terms of preservation of the environment, social well-being and economic resilience are of great importance. With the useful life of a single plant often exceeding 100 years, new hydropower projects could reach millions of families in large regions for several generations. Furthermore, demand for small-scale power generation in Mexico is significant. At the end of 2016, there were approximately 1.8 million inhabitants without access to electricity in rural communities, mainly due to their dispersion in mountainous areas. A part of this population could be served by generation from RES and SHP in particular.[17] At the same time, public awareness of the potential and objective impacts of SHP development is very limited, and prone to ideological and political manipulation promoted by competing industries. Even among professionals and energy sector officials, in Mexico it is not unusual to hear opinions stating that there is no more room for hydropower development, due to its supposed negative environmental and social effects.

RENEWABLE ENERGY POLICY

The regulation of the sustainable management of energy, clean energy obligations and the efficient use of energy is carried out by SENER, which is also involved in promoting the gradual energy transition in Mexico in compliance with relevant international agreements.[24]

Long-term goals established by existing legislation to raise the share of electricity generation from clean energy, including renewable and non-renewable sources, stipulated a 25 per cent share in 2018, a 30 per cent share in 2021, 35 per cent in 2024, 43 per cent in 2030 and 50 per cent in 2050.[11] As of 2021, Mexico had fallen behind on these targets. There are no explicitly defined targets for generation from clean RES.

Currently, projections for greenhouse gas (GHG) emissions associated with fossil fuel-based electricity generation in Mexico predict an increase from 84 $MtCO_2e$ in 2020 to 99 $MtCO_2e$ in 2034. The GHG emission factor of electricity from the SEN in 2020 was 0.494 tCO_2e/MWh.[11] The key legal frameworks shaping the policies of Mexico targeting GHG reduction include the Paris Climate Agreement, signed on 22 April 2016 and committing the country to a 22 per cent reduction by 2030, relative to the 2013 levels. There are other instruments reinforcing these policies, including the National Climate Change Strategy and the Transition Strategy to Promote the Use of Cleaner Technologies and Fuels. The goals outlined by these policies include increasing the scale and efficiency of generation from hydropower through the proper management of dams, the repowering of existing turbines and an increase in the number of hydropower plants. At the same time, distributed generation is a preferable option for rural areas, households, micro- and small businesses or shops in pursuit of a socially conscious energy transition.[11]

While there is no feed-in tariff (FIT) incentive scheme for RES in Mexico, there are other forms of incentivization. These include a 100 per cent tax deduction on the purchase of machinery and equipment for generation from RES, as well as a reduction of income tax for enterprises with projects on RES research and technology development.[37] Another incentive is a minimum required proportion of clean energy for participants in MEM transactions. It was set at 5 per cent of total electricity sold at the point of consumption in 2018, 5.8 per cent in 2019, 7.4 per cent in 2020, 10.9 per cent in 2021 and 13.9 per cent in 2022.[38,39] Finally, the requirement for a generation permit is waived for plants under 500 kW capacity.

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

The main legislation and regulations related to SHP were adjusted in the Energy Reform of 2013. These include the following:

- Political Constitution of Mexico (CPEUM);
- Law of the Electric Industry (LIE);
- Law of Energy Transition (LTE);
- Law of the Federal Commission of Electricity (LCFE);
- General Law of Ecological Balance and Environmental Protection (LGEEPA);
- Law of National Waters (LAN);
- Law of the Regulatory Commission of Energy (LCRE);
- General Law on Climate Change (LGCC).

The licensing process for SHP plants includes a sequence of steps starting with the creation of an enterprise and proceeding with federal permits in the environment, culture, indigenous people, water and electricity and energy sectors. In some cases, state-level environmental authorities may be involved rather than those at the federal level. Municipal authorities are involved in the site selection process for each of the project components. Specific licences required for SHP construction include the following:

- Constitutive act of the enterprise, with a Notary Public and Fiscal authority (SAT);
- Environmental impact assessment (EIA), with SEMARNAT, which includes a preventive report, particular EIA or regional EIA, depending on the project size, as well as a report on the land use change of forested land;
- Indigenous consultation with the Secretariat of the Interior (SEGOB);
- Water authorizations, with CONAGUA, including a surface water concession, federal zone use permit and a permit to carry out hydraulic infrastructure works in waterways and federal areas;
- Study of electric installations for power plants, with CRE, including a contract for interconnections;
- Municipal construction permits, with one or more municipalities involved;
- Power generation permit, with CRE.

The duration of the licensing process is very dependent on the attributes of each project, ranging between 18 and 30 months. The process can be costly due to the various detailed studies and designs which are required.[40]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

Entities involved in the financing of SHP in Mexico include the following:

- Commercial banks;
- National development banks and programmes: Banobras, Nacional Financiera, FIRA;
- Multilateral development banks: World Bank, Inter-American Development Bank, Development Bank of Latin America and others;
- Private RES investment funds;
- Foreign export credit agencies (ECA);
- International cooperation agencies for rural RES projects;
- Equipment suppliers' credit.

Specific programmes targeting SHP development include funding by the National Council of Science and Technology (Conacyt), which issues annual calls for proposals of applied research and development projects related to the implementation of RES, emphasizing the participation of rural communities. Additionally, there is a technical cooperation agreement signed between Government entities of Mexico and China, involving the International Center on Small Hydro Power (ICSHP) of China and the National Institute of Electricity and Clean Energies (INEEL) of Mexico, as well as the Mexican Institute of Water Technology (IMTA), for a two-year programme starting in December 2020. From 2016 to 2019, IMTA led the Iberoamerican Thematic Network on Small-Scale Hydropower (REDHIDRO), which involved the participation of 19 groups from 11 countries in the region.[38]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Barriers to the development of SHP in Mexico include a variety of environmental, socio-political, regulatory, technical and financial factors:

- Environmental: a lack of a reliable national inventory of hydropower potential, unreliable official estimates and the lack of studies on integrated water resources management that incorporates SHP projects;
- Political and social: policies that favour other conventional and RES generation technologies, campaigns against SHP by pressure groups tied to competing commercial interests, a negative social perception of SHP due to lack of accurate information, insecurity in certain regions and disproportionate demands for compensation by some potential host communities;
- Regulatory: a convoluted licensing process, restrictions in regulated areas, delays in receiving indigenous

permits due to understaffing of responsible agencies, difficulties with receiving permits for development on existing infrastructure and risks associated with new upstream developments or legal challenges to ongoing or completed projects;
- Technical: the lack of accurate information on the grid as well as limited grid coverage and capacity, partial lack of specialized personnel, technical deficiencies in SHP projects at the pre-feasibility study phase and lack of domestic manufacturing capacity for SHP plant parts and equipment;
- Financial: the growing cost of the transmission service, lack of coverage and maintenance of access roads in areas with high hydropower potential, charges based on the volume of water used rather than the energy generated, lack of FITs coupled with the low electricity purchase price and a risk of further decline in prices due to auctions, demanding terms of commercial credit, lack of financing for prospection and pre-feasibility studies, difficulties in accessing GHG emissions reduction payments and the difficulty of valuation of positive externalities of SHP development.

Enablers for SHP development in Mexico can likewise be thought of in terms of the following broad categories:
- Environmental: abundant, if not rigorously quantified, potential as well the gradually declining domestic reserves of fossil fuels that Mexico highly depends on;
- Political: the imperative for achieving energy sovereignty, international and domestic commitments to GHG reductions and RES development, and the expectation of Mexican consumers of continuing low electricity prices;
- Domestic and international economy: increasing per capita consumption of electricity, unfulfilled electricity demand of certain communities and attractive export prices for electricity in the region;
- Regulatory and financial incentives: tax breaks and reductions, prioritization of grid connections for RES, ability to sell electricity directly to end users and waiver of generation permit for plants under 500 kW capacity;
- Technical: increasing incorporation of plants of intermittent generation into the grid, availability of skilled personnel in the construction and electrical power sectors and international technical cooperation agreements in the hydropower sector.

KEY FACTS

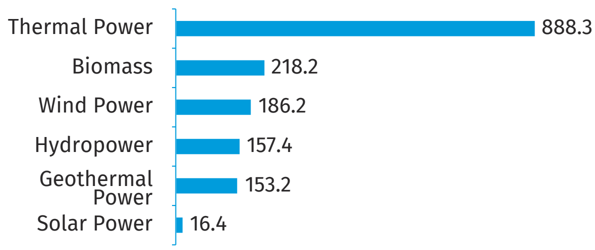
Population	6,624,554 (2020)[1]
Area	130,370 km[2 2]
Topography	The western part of the country is characterized by valleys dissected by low rugged mountains, including the Cordillera Entre Ríos, Cordilleras Isabelia and Dariense, Huapí, Amerrique and Yolaina. In the Cordillera Entre Ríos lies the highest peak of the country, Mogotón Peak at 2,103 metres. A string of 40 volcanoes, some of which are active, stretches from north-west to south-east along the Pacific coast. The eastern part of the country consists of wide low plains reaching 100 kilometres in width.[2]
Climate	In the east of Nicaragua, the climate is slightly cooler and wetter than in the west. The Pacific side of the country has two seasons: a rainy season, lasting from May to November, and a dry season, lasting from December to April. On the Caribbean side, the dry season is from March to May, while the rainy season lasts for nine months. Annual temperatures across the country average 27 °C. However, in the northern mountains the climate is cooler with an average temperature of 18 °C.[2]
Climate Change	As global temperatures rise, the natural cycle between dry and wet seasons in Nicaragua is anticipated to become more severe, causing increases in both droughts and floods. As a result, disasters such as landslides and fires, particularly in the rural regions, are expected to become more prevalent. In addition, the water temperature of lakes and rivers has been rising and will continue to do so, which will affect water quality and thermal structure.[3]
Rain Pattern	Annual precipitation averages 1,905 mm on the Pacific side of the country and 3,810 mm on the Caribbean side.[2]
Hydrology	The central mountains of Nicaragua form the main watershed. The rivers flowing to the west of it are relatively short and drain into the Pacific Ocean or Lakes Managua and Nicaragua. The west is the region where the major lakes are located, with Lake Nicaragua being the largest lake in Central America. The most important rivers in this part of the country are the Negro, Estero Real and Tamarindo. The rivers to the east of the mountains tend to be longer and empty into the Caribbean. The main rivers here are the Coco (475 km), Río Grande de Matagalpa (430 km), Prinzapolka (254 km), San Juan (200 km), Indio (90 km), Escondido (89 km) and Maíz (60 km).[2]

ELECTRICITY SECTOR OVERVIEW

In 2020, electricity generation in Nicaragua was approximately 3,797 GWh, 71 per cent of which was sourced from renewable energy. Thermal power, primarily fuel oil and diesel, accounted for 29 per cent, geothermal power for 21 per cent, biomass for approximately 19 per cent, hydropower for just above 15 per cent, wind power for almost 15 per cent and solar power for the remaining almost 1 per cent (Figure 1).[4,5] An additional 1,071 GWh of electricity was imported, and none was exported during 2020.[6]

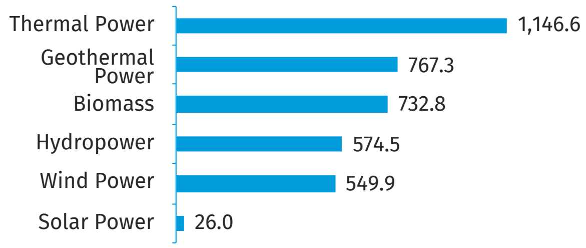
As of December 2020, the total installed capacity of Nicaragua was approximately 1,620 MW. Thermal power accounted for the majority at almost 55 per cent of the total installed capacity, biomass accounted for approximately 13 per cent, wind power for 11 per cent, geothermal power and hydropower for approximately 10 per cent each and solar power for just under 1 per cent (Figure 2).[7] Approximately 99 per cent of the total installed capacity fed the National Interconnected System, which serves the mainland, whereas the National Island System accounted for the remaining 1 per cent of capacity. While the mainland uses a mix of all of these six sources, the island system relies on just thermal power (88 per cent) and solar power (12 per cent). The total available capacity of the country's electricity system was 18 per cent lower than installed capacity, at 1,329 MW.[7]

Figure 1. **Annual Electricity Generation by Source in Nicaragua in 2020 (GWh)**



Source: INE[5]

Figure 2. **Installed Electricity Capacity by Source in Nicaragua in 2020 (MW)**

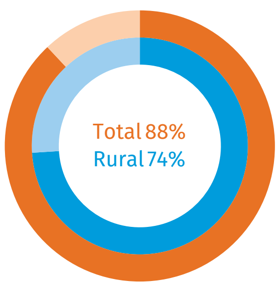


Source: INE[7]

In the 1990s, the electricity sector of Nicaragua underwent a restructuring, whereby the state-owned Nicaraguan Electricity Company (ENEL) was unbundled and partially privatized. The reform resulted in the creation of four generation companies (GEMOSA, GEOSA, HIDROGESA and GECSA), two distribution companies (DISNORTE and DISSUR) and one transmission company (ENTRESA). Two of the generation companies, HIDROGESA and GECSA, were kept public, while GEMOSA and GEOSA fully privatized. In the years since the initial breakup of ENEL, several smaller private generation companies have been established. Electricity transmission remains public, fully managed by state-owned ENTRESA. The two distribution companies were sold to the Spanish company Unión Fenosa, which originally covered the western, central and northern parts of the country, while the ENEL remained responsible for the eastern regions. [8] Since the beginning of the 2000s, however, new private distribution companies have been created and have acquired concession over many of the regions. Currently, there are 17 concessional areas of electricity distribution serviced by 14 different companies.[9]

The electricity sector is regulated by the Nicaraguan Energy Institute (INE). The National Load Dispatch Committee (CNDC) is the electricity market operator and the Ministry of Energy and Mines (MEM) oversees energy policy and planning. Electricity is traded in spot and wholesale markets, which allows the trading of electricity through long-term contracts between generating companies and distributing companies or large users.[10]

Figure 3. **Electrification Rate in Nicaragua in 2020 (%)**



Source: World Bank[12]

In recent years, the electricity sector of Nicaragua has been prioritized in national plans and initiatives such as the Rural Electrification Policy of 2005 as well as in the Sustainable Energy for All initiative of 2012. The Government has made significant efforts to improve the reliability of electricity supply as well as access in vulnerable areas.[11] The overall electrification rate in Nicaragua reached 88 per cent in 2019, with over 99 per cent in urban areas and 74 per cent in rural areas (Figure 3).[12]

Electricity tariffs vary with type, usage and distribution concession. The most common tariffs carried out by DISNORTE and DISSUR as of February 2022 are as shown in Table 1. For low-income households that use less than 150 kWh, a subsidized tariff is available.[13]

Table 1. **Electricity Tariffs in Nicaragua**

Type	*Usage*	*Cost (USD/kWh)*
Residential	*First 25 kWh*	*0.07*
	Next 25 kWh	*0.16*
	Next 50 kWh	*0.17*
	Next 50 kWh	*0.23*
	Next 350 kWh	*0.23*
	Next 500 kWh	*0.36*
	Additional above 1,000 kWh	*0.41*
Commercial	*Contracted with less than 25 kW*	*0.17*
	Contracted with more than 25 kW	*0.18*
Industrial	*Contracted with less than 25 kW*	*0.15*
	Contracted with more than 25 kW	*0.17*

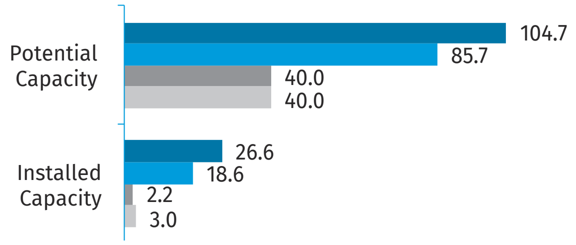
SMALL HYDROPOWER SECTOR OVERVIEW

The definition of small hydropower (SHP) in Nicaragua is up to 10 MW. The installed capacity of SHP was 26.6 MW in 2019, while the potential is estimated to be 104.7 MW, indicating that approximately 25 per cent has been developed.[14,15] Compared to the World Small Hydropower Development Report (WSHPDR) 2019, installed capacity has increased by 44 per cent, a total of 8.0 MW (Figure 4). This is a result of the completion of three additional plants: 5.70 MW San Martin, 1.48 MW Yakalwas and 0.85 MW La Camaleona. Furthermore, due to the identification of another three locations to develop SHP in the upcoming years, total potential capacity has also increased by 19 MW.

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Nicaragua (MW)**



Source: MEM,[14] MEM,[15] WSHPDR 2019,[16] WSHPDR 2016,[17] WSHPDR 2013[18]

As of 2019, there were 17 operational SHP plants with a combined capacity of 26.64 MW (Table 1). There are another 20 potential sites throughout Nicaragua that are planned to be developed in the future, totaling 78.01 MW (Table 2).

Table 1. **List of Existing Small Hydropower Plants in Nicaragua**

Name	*Location*	*Capacity (MW)*
San Martin	El Tuma-La Dalia, Matagalpa	5.70

RENEWABLE ENERGY POLICY

The Government of Nicaragua aims to increase the share of renewable energy sources (hydropower, wind power, solar power, biomass and geothermal power) in the energy mix. The commitment began in the early 2000s, when a series of policies and laws were first implemented. The National Energy Policy of 2004 established the policy framework for the promotion of renewable energy. In 2005, Law 532 on the Promotion of Electricity Generation with Renewable Resources declared that it is of national interest to generate electricity using renewable energy sources. The Law also provides financial incentives to encourage the establishment of renewable energy plants including exemption of import taxes, local taxes, value added taxes and income taxes for the first seven years of a new energy plant's life. It also obligates utilities to buy energy from renewable energy plants via a bidding process.[19]

Intertwining the goals to increase renewable energy as well as to increase general access to electricity, in 2005 the country released the Rural Electrification Policy, which promotes the expansion of electricity to rural areas, with special prioritization on using renewable sources.[19] To complement this policy, Law 554 on Energy Stability passed in 2005, defined measures to ensure that energy is available to all income levels, providing subsidies to residential usage of 150 kWh or less per month, and created the Fund for Energy Development and the Energy Crisis Fund, all of which prioritizes renewable energy. The law further insists that the Government should seek international funding for renewable energy generation projects.[20]

The Plan for Electricity Generation Expansion 2016–2030 provides a comprehensive set of plans and goals for the country's electricity sector. The plan outlined the expectation that by 2030, an additional 1,223 MW of new capacity will be added to the country's electricity system. This includes 138 MW of biomass, 74 MW of solar photovoltaics (PV), 143 MW of wind power, 135 MW of geothermal power, 271 MW of reservoir-based hydropower and 22 MW of run-of-river hydropower capacity. However, the plan also foresees 440 MW of new thermal power capacity, consisting of fuel oil and natural gas plants. Nonetheless, the plan's goal was to reduce the share of thermal power generation in the country's energy mix from 45 per cent in 2018 to 36 per cent in 2023 and to 27 per cent in 2030, with the remaining share being from renewable energy.[21] In 2020, the actual electricity generation in the country was 29 per cent thermal energy and 71 per cent renewable energy, demonstrating steady progress towards the 2030 goal.[5]

Among all renewable energy sources, hydropower is expected to see the greatest addition of new capacity in the coming decade according to the plan. In general, the Government has declared hydropower development to be an important part of its energy policy and a favourable legal framework and an attractive incentive structure have been established for hydropower projects up to 5 MW.[10]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

Law 476 for the Promotion of the Hydroelectric Subsector stipulates that hydropower projects below 1 MW do not need a water concession. Instead, producers can obtain a permit for a period of 15 years. For plants with capacities of 1–5 MW, a simplified procedure applies for obtaining a water concession from the Ministry of Development, Industry and Trade. Additionally, Law 217 for the Protection of Environment and Natural Resources stipulates that projects with capacities below 5 MW do not need an environmental impact assessment.[10]

COST OF SMALL HYDROPOWER DEVELOPMENT

The costs associated with the development of SHP plants in Nicaragua are site-specific and depend on various factors. The total costs of three hydropower projects that were completed in 2018 are shown in Table 3.

Table 3. **Costs of Selected Small Hydropower Projects in Nicaragua**

Name	*Capacity (MW)*	*Total cost (USD million)*	*Cost per MW (USD million/MW)*
San Martin	5.70	19.4	3.4
Yakalwas	1.48	7.5	5.0
La Camaleona	0.85	3.8	4.4

Source: MEM[15]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

SHP development in Nicaragua is mainly financed by private investors, international firms, or international organizations such as the European Investment Bank, the Inter-American Investment Bank and the Central American Bank for Economic Integration. The county's investment promotion agency, PRONicaragua, is an integral part of foreign direct investment and facilitates the process with potential investors.[22]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The Plan for Electricity Generation Expansion 2016–2030 expresses concern for the effects of climate change on the country's hydropower. Due to the increased prevalence of droughts expected by 2030, the contribution of natural water resources to hydropower plants may decrease by up to 13 per cent. This decrease in input could possibly result in an up to 30 per cent decrease in power generation.[21]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Barriers hindering the development of SHP in Nicaragua include:

- Difficulty in accessing funding because of the high initial cost of projects. Commercial finance is needed over the long-term, but, in general, financial assistance is short-term with high interest rates;
- The duration of power purchase agreements is too short to motivate SHP project development. Therefore, it is difficult to make long-term investment decisions;

- The approved fiscal incentives for hydropower projects do not create a level playing field for hydropower development compared to thermal power projects, since the latter continue to be highly subsidized;
- Lack of experience and technological knowledge in the implementation of SHP plants.[10,17]

Enablers encouraging the development of SHP in Nicaragua include:

- Strong presence of political will and dedication to the transition to renewable energy and climate action;
- Very limited restrictions to foreign direct investment in the energy sector;
- Between lakes, lagoons and rivers, the country's surface area is 10 per cent water, offering great possibilities to explore for more potential hydropower sites;
- It has been estimated that there is approximately 3,760 MW of total potential of hydropower generation throughout the country given a 100 per cent plant availability scenario, larger than any other renewable resource in the country. Currently less than 5 per cent of that is being utilized leaving an abundance of untapped potential;
- As rural electrification is underway, electricity demand is expected to increase accordingly.[10,22]

Panama

José Fábrega,[a,b] Denise Delvalle,[a,b] and Alexis Baúles[b] National Research System of Panama (SNI)[a,b] Hydraulic and Hydrotechnical Research Center, Universidad Tecnológica de Panamá

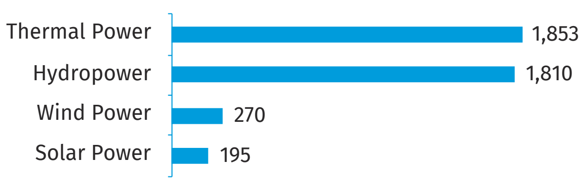
KEY FACTS

Population	4,218,808 (2019)[1]
Area	75,420 km^2 [2]
Topography	There are rugged mountains to the west and towards the Caribbean Sea and rolling hills and vast plains by the Pacific Coast. The lowlands cover approximately 70 per cent of the country's territory. The highest point in Panama is the Volcán Barú, which rises to 3,475 metres above sea level.[2]
Climate	Panama has a tropical climate with two seasons, dry and rainy. The variations in climatic conditions depend on the region and the altitude. Winter is the wet season and lasts from May to November, while summer is the dry season and lasts from December to April, with March and April ordinarily being the warmest months. The annual average temperature in Panama ranges between 23 °C and 27 °C for the coastal areas and in the interior, while at higher altitudes it can drop to 19 °C. In general, temperatures are reflective of the country's tropical climate profile and increase 0.56 °C for every 100 metres of altitude. [3]
Climate Change	Observed climate change impacts in Panama have included intense rains during the dry season, long periods of drought and sea level rise. Increased energy demand driven by rising temperatures has also been observed. The projected climate change impacts by the end of the 21st century include loss of crops and soils, loss of the coastline as a result of storm surges, as well as more severe flooding in large urban centres, with damage to infrastructure and services.[4]
Rain Pattern	Panama has a yearly average precipitation of 2,928 mm. The Pacific region shows a wet season pattern from May to November. For the Atlantic region, precipitation is continuous throughout the year.[5,6]
Hydrology	There are approximately 500 rivers in Panama in 52 watersheds. Seventy per cent of the rivers, including most of the longer streams, run to the Pacific coast, while 30 per cent run to the Atlantic coast.[7]

ELECTRICITY SECTOR OVERVIEW

The total installed electricity capacity of Panama was 4,128 MW in 2020, representing a 26 per cent increase since 2017. Thermal power plants provided 1,853 MW (45 per cent) of the total, hydropower provided 1,810 MW (44 per cent), wind power provided 270 MW (7 per cent) and solar power provided 195 MW (5 per cent) (Figure 1).[8]

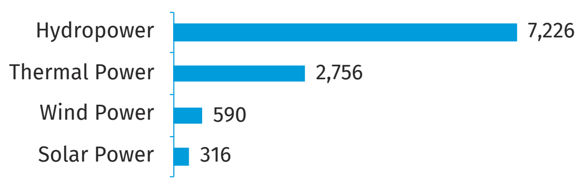
Figure 1. **Installed Electricity Capacity by Source in Panama in 2020 (MW)**



Source: ASEP[8]

Annual generation of electricity in Panama in 2020 amounted to approximately 10,887 GWh. Hydropower accounted for 7,226 GWh (66 per cent) of the total, thermal power accounted for 2,756 GWh (25 per cent), wind power accounted for 590 GWh (5 per cent) and solar power accounted for 316 GWh (3 per cent) (Figure 2). Renewable energy sources (RES) thus accounted for 74 per cent of all electricity generation in the country in 2020. Exports of electricity in 2020 amounted to 524 GWh, while imports were 86 GWh.[8]

Figure 2. **Annual Electricity Generation by Source in Panama in 2020 (GWh)**

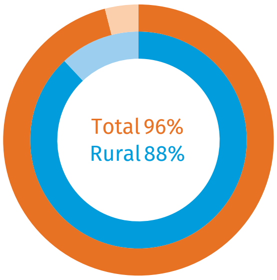


Source: ASEP[8]

Note: Values were calculated based on percentages quoted in the source.

The nationwide rate of electricity access in Panama was nearly 96 per cent in 2019 and 88 per cent in rural areas (Figure 3).[9] Electricity consumption in 2020 amounted to 9,521 GWh and an additional 125 GWh were accounted for by self-consumption.[10]

Figure 3. **Electrification Rate in Panama in 2019 (%)**



Source: World Bank[9]

The National Secretariat of Energy, established by Law 43 on 23 April 2018, is responsible for overseeing the energy sector in Panama.[11] The Rural Electrification Office (OER), operating under the supervision of the Ministry of Public Works, is tasked with providing energy to rural, isolated areas not connected to the national grid. The OER works to increase electricity access in rural areas both by extending electrical networks as well as by developing local generating capacity through projects employing RES, including small hydropower (SHP).[12,13]

Key legislation regulating the energy sector in Panama includes Law No. 6 introduced on 3 February 1997 (and its later amendments) as well as Decree Law No. 22 of 1998.[11,14,15,16] Following the privatization of the public electricity utility in 1998, the Electric Transmission Company (ETESA), a public limited company, was put in charge of the transmission and distribution of electricity. ETESA is additionally responsible for grid expansion planning, construction of new transmission and distribution lines and grid maintenance.[17] The remuneration for the services carried out by ETESA is likewise regulated by Law No. 6 of 1997.[14]

The electricity grid of Panama consists of three main transmission lines, all located along the Pacific coast. All three lines are complete, fully operational and operating at full capacity.[17] Targets for the ongoing and future expansion of the electricity grid are outlined in the National Interconnected System Expansion Plan 2019–2033. The Plan consists of three major documents:

- Basic studies including forecasts of energy demand and power at the level of the Main Transmission System;
- The Indicative Generation Plan, the objective of which is to provide information on the expansion of generation capacities and the evolution of the generation sector, as well as to provide an analysis of the current supply situation and potential energy alternatives, taking into account multiple variables including energy demand and resources, hydrology, and availability and costs of fuels, among others;
- The Expansion Plan of the Transmission System, which will become mandatory once approved by the National Public Service Authority (ASEP).[18]

Additionally, Panama is developing interconnection strategies with neighbouring countries in Central America through the Central American Electric Interconnection System (SIEPAC). This system was officially inaugurated in December 2014 and includes Guatemala, Honduras, Nicaragua, El Salvador, Costa Rica and Panama. With an investment of USD 500 million USD, the system consists of one line of 230 kV connected to capacities of 300 MW. This initiative has great potential, although exchanges have been very modest so far. A separate integration plan with Colombia has also been proposed, which is expected to produce price advantages and involves the introduction of a virtual generator with a capacity of 400 MW.[19,20]

The largest independent electricity producers in Panama as of 2020 were Minera Panama mining company with an installed capacity of 300 MW and the Panama Canal Authority with an installed capacity of 213 MW, 72 per cent of which was provided by thermal power plants and 28 per cent by hydropower plants.[8,21]

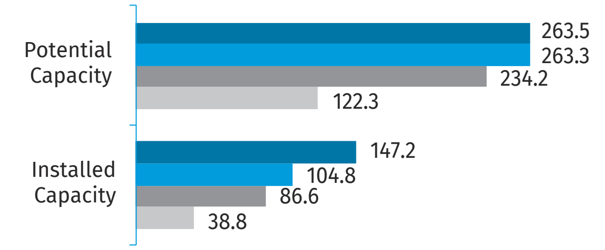
Electricity tariffs in Panama are set on a monthly basis by the ASEP and include a variable price that fluctuates with the fuel market prices. From 2016 to 2021, the average electricity tariff in Panama fluctuated between 0.163 USD/kWh to 0.217 USD/kWh before subsidies. Subsidized electricity tariffs have ranged from a low of 0.149 USD/kWh in December 2020 to a high of 0.187 USD/kWh in December 2019.[22]

SMALL HYDROPOWER SECTOR OVERVIEW

The Latin American Energy Organization (OLADE) defines SHP plants as hydropower plants with a capacity of up to 5 MW, while the legal framework of Panama provides incentives for hydropower plants up to 20 MW.[23,24] However, for the sake of comparison with previous editions of the World Small Hydropower Development Report (WSHPDR), the current report uses the up to 10 MW definition for SHP.

The total installed SHP capacity up to 10 MW in Panama was 147.2 MW as of March 2021, provided by 24 SHP plants, while an additional 116.2 MW were available in the form of ongoing and planned SHP projects as well as potential SHP sites.[25,26] The total SHP potential capacity of the country is thus estimated at nearly 263.5 MW. Relative to the WSHPDR 2019, installed SHP capacity in the country has increased by 40 per cent due to the construction of several new SHP plants. Potential capacity has meanwhile remained virtually unchanged, as ongoing development has included previously-identified potential sites. (Figure 4).[27] A partial list of existing SHP plants is provided in Table 1.

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Panama (MW)**



Source: ASEP,[25,26] WSHPDR 2019,[27] WSHPDR 2013,[28] WSHPDR 2016[29]

There was a total of nine SHP projects in various stages of development in Panama as of 2021, with a planned capacity of 52.4 MW.[26] However, many of them are currently suspended, with the proposed launch dates no longer relevant. Several of the ongoing projects are listed in Table 2.

Table 2. **List of Selected Ongoing Small Hydropower Projects in Panama**

Name	*Location*	*Capacity (MW)*	*Developer*	*Planned launch year*	*Development stage*
Chuspa	Chiriquí, Boquerón, Paraiso y Guayabal	10.00	Navitas International, S.A.	2020	Under construction

RENEWABLE ENERGY POLICY

Panama has committed to achieving Sustainable Development Goal (SDG) 7 through promoting an energy transition policy and electric mobility. Likewise, Panama ratified the Paris Climate Change Agreement (PCCA) in September 2016, committing itself to reducing greenhouse gas (GHG) emissions.[30] The National Determined Contribution (NDC) of Panama set a target of increasing electricity generation from RES by 30 per cent by the end of 2050, relative to 2014. In 2020, Panama presented an updated NDC, which included targets of an 11.5 per cent emissions reduction by 2030 and a 24 per cent reduction by 2050, relative to the trend under the business-as-usual scenario.[31]

In addition to international agreements on GHG reductions and sustainable development, the commitment of Panama to RES development is motivated by rising electricity demand and the high cost of electricity in the country. In April 2011, Law No. 44 was adopted with the aim of promoting various forms of RES with a particular focus on wind power. The law provides for the application of long-range modelling of alternative energy development strategies in a variety of possible combinations. The Law was further developed with the passage of Law No. 18 in March 2013.[15,32]

The COVID-19 pandemic has contributed to delays in the implementation of ongoing projects and the development of new projects in the electricity sector, resulting in a negative impact on the national electricity market. Two new regulations, MIPRE-2020-0015448 and its modification MIPRE-2021-002034, were adopted between 2020 and 2021 to address this issue and guarantee the security of the electricity supply by outlining measures for short-term contracting of power and energy.[33,34]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

Along with promoting other RES, Law No. 45-2004 established incentives for SHP projects of up to 20 MW capacity. These include:

- SHP plants up to 10 MW are allowed to sell generated electricity both directly and indirectly;
- SHP projects between 10 MW and 20 MW are exempt from paying import taxes and levies on the first delivered 10 MW for 10 years, including the Tax on the Transfer of Personal Property and Provision of Services for the importation of equipment, machinery, materials and spare parts;
- SHP projects up to 10 MW can qualify for a subsidy of the original investment costs of up to 25 per cent, calculated in terms of a reduction of equivalent tons of CO_2 emissions per year, as well as a tax exemption of up to 5 per cent of the total value of direct investment in connected infrastructure to be transferred to public ownership (roads, bridges, sewer lines, etc.).[24]

COST OF SMALL HYDROPOWER DEVELOPMENT

SHP development in Panama relies primarily on the private sector. The construction cost of the 4.95 MW Los Planetas-1 SHP plant in Chiriqui province was USD 21.3 million, or 4,303 USD/kW.[35] Meanwhile, the estimated value of the 6.3 MW Bajos de Toluma SHP plant was USD 22.4 million in 2017, or 3,556 USD/kW.[36]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Although there is a favourable legal framework in Panama granting fiscal incentives to SHP plants, development of the SHP sector is not significant.

The most important barrier to SHP development in the country is the lack of interest from private finance in supporting investment in SHP. As a result, rural communities are almost exclusively dependent on state financing for electricity sector development, including SHP.

Factors enabling SHP development in the country include:

- A solidly established hydropower sector with many operational SHP plants, most constructed in the last few decades;
- Fiscal incentives in the form of tax exemptions provided for SHP;
- Existing SHP projects that have stalled at various stages of implementation and may welcome additional financing;
- An abundance of identified prospective sites for new SHP development.

2.3. South America

Countries: Argentina, Bolivia, Brazil, Chile, Colombia, Ecuador, French Guiana, Guyana, Paraguay, Peru, Suriname, Uruguay, Venezuela

INTRODUCTION TO THE REGION

Electricity generation in South America is dominated by thermal power and large hydropower. Brazil is the largest electricity producer in South America and accounts for approximately half of the region's total installed capacity and 60 per cent of the installed hydropower capacity. Brazil, Argentina, Chile, Peru and Uruguay all have highly diversified electricity sectors with significant installed capacities of solar power, wind power, bioenergy and other renewable energy sources (RES) supplementing hydropower and thermal power capacities. In addition, Brazil and Argentina operate the only nuclear power plants in the region. Other countries in South America rely primarily on a mix of hydropower and thermal power, with RES other than hydropower playing a relatively minor role.

Hydropower plays a particularly prominent role as the single largest source of electricity generation in Brazil, Colombia, Ecuador, Paraguay, Peru and Uruguay. In Paraguay, hydropower accounts for nearly 100 per cent of installed capacity and annual electricity generation and enables the country to export more than half of its annual electricity production to Brazil and Argentina. In other countries in the region, thermal power is the dominant energy source, while hydropower plays a supplementary role, with the exception of Guyana, where the installed capacity and annual generation of hydropower are negligible. Under the framework of the Renewables in Latin America and the Caribbean (RELAC) initiative, 12 countries in the region have committed to achieving a 70 per cent share of renewable energy sources in the regional energy mix by 2030, with hydropower expected to play a key role. Brazil is expected to continue to dominate the hydropower sector of South America through the current decade.

Electricity access is high across South America, at or approaching 100 per cent in most countries in the region. There is a high degree of cooperation among countries in cross-border power transmission and generation of electricity. For example, Bolivia, Chile, Colombia, Ecuador and Peru participate in the Andean Interconnection System (SINEA), which aims to integrate the regulatory frameworks, interconnections and electricity markets of the member states, while Paraguay operates several hydropower plants jointly with Brazil and Argentina.

An overview of the electricity sectors of the countries in the region is provided in Table 1.

Table 1. **Overview of South America**

Country	*Total population (million people)*	*Electricity access, total (%)*	*Electricity access, rural (%)*	*Total installed capacity (MW)*	*Electricity generation (GWh/year)*	*Hydropower installed capacity (MW)*	*Hydropower generation (GWh/year)*
Argentina	45	100	100	41,952	134,177	11,344	30,350
Bolivia	12	88	72	3,484	9,531	1,073	3,251
Brazil	212	100	100	177,300	626,300	109,315	397,900
Chile	19	N/A	N/A	26,653	70,828	6,806	18,263

Note: Data in the table are based on data contained in individual country chapters of the *WSHPDR 2022*; years may vary.

REGIONAL SMALL HYDROPOWER OVERVIEW

The definition of small hydropower (SHP) in South America varies from country to country. The up to 10 MW definition is used in Ecuador and French Guiana, while Bolivia and Guyana have both adopted the up to 5 MW definition in line with the definition proposed by the Latin American Energy Organization (OLADE). For other countries in the region, the definition of SHP includes larger plants. Chile, Colombia and Peru define SHP as plants of up to 20 MW, Brazil uses the up to 30 MW definition, and Argentina, Paraguay and Uruguay use the up to 50 MW definition. No official definition of SHP exists in Suriname or Venezuela.

A comparison of installed and potential SHP capacities in the region is provided in Table 2.

Table 2. **Small Hydropower Capacities by Country in (MW)**

Country	*Local SHP definition*	*Installed capacity (local def.)*	*Potential capacity (local def.)*	*Installed capacity (≤10 MW)*	*Potential capacity (≤10 MW)*
Argentina	Up to 50 MW	510.0	N/A	97.0	430.0
Bolivia	Up to 5 MW	N/A	N/A	99.1	99.1*
Brazil	Up to 30 MW	6,324.6	35,765.0	1,608.2	3,737.8
Chile	Up to 20 MW	618.0	5,145.0	304.0	2,995.0
Colombia	Up to 20 MW	900.8	N/A	234.6	4,946.0
Ecuador	Up to 10 MW	112.7	356.3	112.7	356.3
French Guiana	Up to 10 MW	5.5	34.5	5.5	34.5
Guyana	Up to 5 MW	0.02	24.2	0.02	92.0
Paraguay	Up to 50 MW	0.0	116.3	0.0	N/A
Peru	Up to 20 MW	503.8	3,500.0	N/A	N/A
Suriname	N/A	N/A	N/A	0.0	2.7
Uruguay	Up to 50 MW	0.0	231.5	0.0	208.0
Venezuela	N/A	N/A	N/A	1.4	49.7
Total	-	-	-	**2,462.6**	**12,951.1**

Source: *WSHPDR 2022*[1]

Note: *Based on installed capacity.

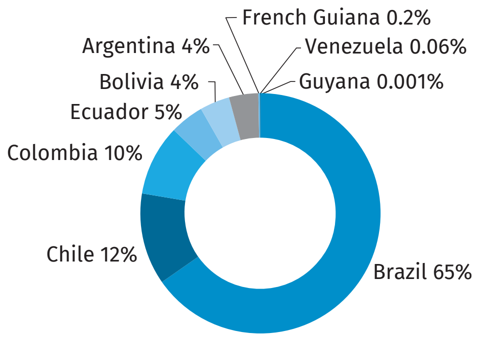
The total installed capacity of SHP of up to 10 MW in South America is 2,462.6 MW, while potential capacity is estimated at 12,951.1 MW. Relative to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed capacity has increased by three times, mainly due to the inclusion of data on the installed capacity for SHP of up to 10 MW in Brazil. At the same time, the potential capacity has decreased by nearly 55 per cent, mainly due to a drastic downward reassessment of the SHP potential of Colombia based on more recent data.

Although hydropower potential in South America is considerable, SHP plays a relatively minor role in the electricity generation mix of most countries in the region due to heavy focus on large hydropower development, accounting for no more than 10 per cent, and usually closer to 2–5 per cent, of the countries' total installed hydropower capacities. The one exception to this pattern is Guyana, where the entire installed hydropower capacity is composed of a single micro-hydropower plant.

Brazil leads the region in installed capacity of SHP of up to 10 MW, and actively pursues SHP development both under the up to 10 MW definition as well as under the local definition of up to 30 MW. Chile, Columbia and Ecuador have also seen considerable recent expansion of SHP capacity off up to 10 MW, while Peru has dramatically increased its capacity of SHP of up to 20 MW. In other countries in the region, significant development in the SHP sector has been lacking and the reported installed SHP capacity of several countries including Bolivia, French Guiana and Suriname has decreased as a result of access to better data.

The national share of regional installed SHP capacity by country is displayed in Figure 1, while the share of total national SHP potential utilized by the countries in the region is displayed in Figure 2.

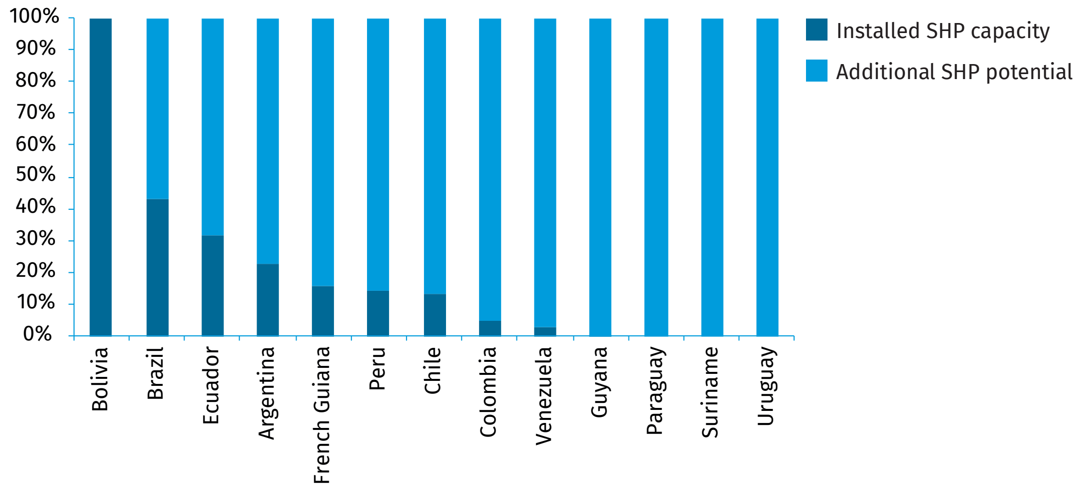
Figure 1. **Share of Regional Installed Capacity of Small Hydropower up to 10 MW by Country in South America (%)**



Source: *WSHPDR 2022*[1]

Note: Paraguay, Suriname and Uruguay are not included due to a lack of installed SHP capacity; Peru is not included due to a lack of data on SHP up to 10 MW.

Figure 2. **Utilized Small Hydropower Potential by Country in South America (%)**



Source: *WSHPDR 2022*[1]

Note: For SHP of up to 10 MW except in the case of Paraguay and Peru, where the local definition is used due to a lack of comprehensive data on SHP of up to 10 MW.

The installed capacity of SHP of up to 10 MW in **Argentina** is 97 MW, provided by 24 plants. The potential capacity is estimated at 430 MW, indicating that nearly 23 per cent has been developed. The SHP sector in the country has not seen any recent development and many existing SHP facilities are in need of modernization. However, several SHP projects are in the planning stages and 116 potential SHP sites have been identified.

The installed capacity of SHP of up to 10 MW in **Bolivia** is 99.1 MW. There is no reliable estimate of potential for SHP off up to 10 MW, although potential for SHP of up to 30 MW has been estimated at 200 MW. There are 13 registered SHP plants in the country, in addition to dozens of unregistered plants operating on isolated grids. Unregistered off-grid SHP plants are particularly widespread in the country's private mining sector. The Government plans to expand SHP capacity by an additional 50 MW, but suitable sites have not been comprehensively catalogued. One additional SHP plant was under construction as of 2019.

In **Brazil**, the installed capacity of SHP under the local definition of up to 30 MW is 6,324.6 MW, while the estimated potential capacity is 35,765 MW, indicating that 18 per cent has been developed. For SHP of up to 10 MW, the installed capacity is 1,608.2 MW, while potential capacity is estimated at 3,737.8 MW, indicating that 43 per cent has been developed. Development of SHP in the country is actively ongoing, with over 20 new plants commissioned in 2020 alone. Construction of new plants is carried out in accordance with targets established by the Ten-Year Plan for Energy Expansion 2029. By 2029, the Government intends to expand the country's total capacity of SHP of up to 30 MW to 9,045 MW.

The installed capacity of SHP of up to 20 MW in **Chile** is 618 MW and estimated potential capacity is 5,145 MW, indicating that 12 per cent has been developed. For SHP of up to 10 MW, the installed capacity is 304 MW and estimated potential capacity is 2,995 MW, indicating that 10 per cent has been developed. SHP development in the country is ongoing, with several new plants commissioned on average every year. Several SHP projects were ongoing as of 2021 and a number of additional projects are in the planning stages.

Colombia has an installed capacity of 900.8 MW for SHP of up to 20 MW and of 234.6 MW for SHP of up to 10 MW. The potential capacity of SHP of up to 10 MW is estimated at 4,946 MW, indicating that nearly 5 per cent has been developed. A large number of new SHP plants have been commissioned in recent years, and 43 prospective SHP projects of up to 10 MW are under review. The reported estimate of the country's SHP potential has been drastically reduced on the basis of updated, more detailed data on regional SHP potential.

The installed capacity for SHP of up to 10 MW in **Ecuador** is 112.7 MW, provided by 43 plants. Potential capacity is estimated at 356.3 MW, indicating that approximately 32 per cent has been developed. Several new SHP plants were constructed in the country between 2016 and 2020, with six additional plants expected to be completed by 2024.

French Guiana has an installed capacity of 5.5 MW for SHP of up to 10 MW, provided by two plants. The estimated potential capacity, based on plans issued by the Government for expansion of the SHP sector to 2030, is 34.5 MW, indicating that 16 per cent has been developed. Despite the established targets, little SHP development has taken place in the country in recent years, although two SHP projects are in the early planning stages.

Guyana has a single micro-hydropower plant with an installed capacity of approximately 0.02 MW. Potential SHP capacity in the country for SHP of up to 10 MW is estimated at 92 MW, which remains almost fully undeveloped. The existing SHP plant was launched in 2019 and is the first operational SHP plant in the country in over 20 years. Five projects involving the rehabilitation of non-operational SHP plants as well as the construction of new plants are in various stages of planning.

Paraguay has no installed SHP capacity, as the country's entire hydropower fleet consist of plants with installed capacities of over 50 MW. The potential capacity for SHP of up to 50 MW is estimated at 116.3 MW and remains fully undeveloped. The estimate of potential capacity is based on the total planned capacity of 18 SHP projects intended to enter into operation between 2029 and 2036.

Peru has an installed capacity of 503.8 MW for SHP of up to 20 MW, while potential capacity is estimated at 3,500 MW, indicating that over 14 per cent has been developed. The country's SHP capacity has increased dramatically in recent years, and at least 11 new plants have been commissioned between 2016 and 2019. There were 24 ongoing SHP projects in Peru as of 2021, with construction to be completed by 2024.

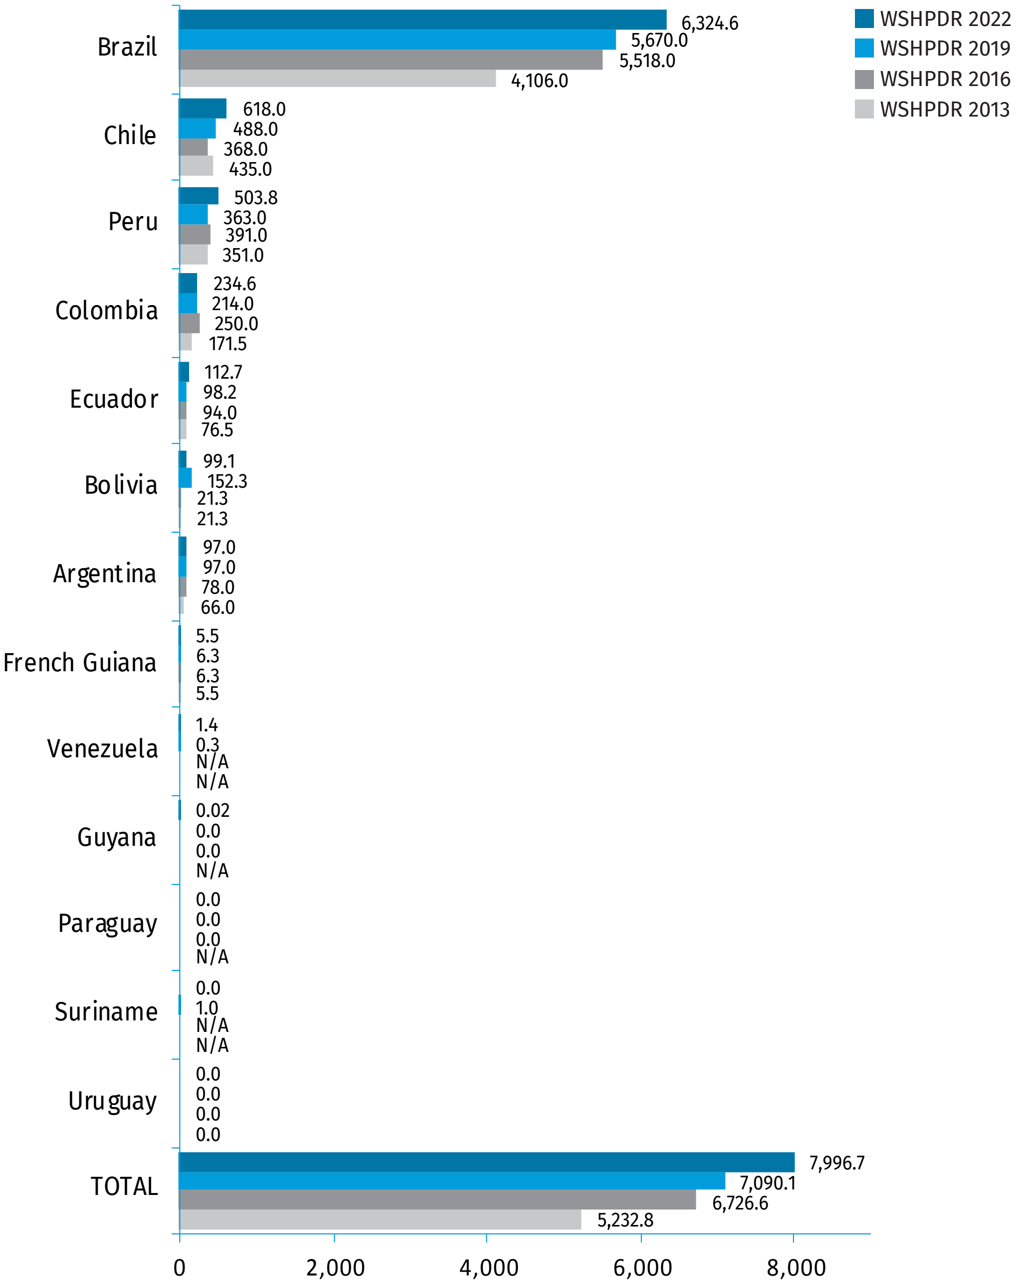
Suriname has no operational SHP capacity, although 2.7 MW of potential for SHP of up to 10 MW has been identified. Several formerly operational SHP plants exist in the country, but there are no known plans for their rehabilitation or for the construction of any new SHP plants.

Uruguay likewise has no installed SHP capacity. Potential capacity for SHP of up to 50 MW is estimated at 231.5 MW, while for SHP of up to 10 MW it is estimated at 208 MW, and remains fully undeveloped. Several studies have been carried out over the last decade assessing the technical and economic feasibility of multiple potential SHP sites, but there are no specific plans for any new SHP construction.

The installed capacity of SHP of up to 10 MW in **Venezuela** is 1.4 MW, provided by seven SHP plants, of which the most recent one was built in 1994. Potential capacity for SHP of up to 10 MW is estimated at 49.7 MW, indicating that 3 per cent has been developed. Ten potential SHP sites have been identified, but there has been little SHP development in recent years and there are no planned or ongoing SHP projects in the country.

Changes in the installed SHP capacities of the countries in the region compared to the previous editions of the *WSHPDR* are displayed in Figure 3.

Figure 3. **Change in Installed Capacity of Small Hydropower from *WSHPDR 2013* to *WSHPDR 2022* by Country in South America (MW)**



Source: *WSHPDR 2022*,[1] *WSHPDR 2013*,[2] *WSHPDR 2016*,[3] *WSHPDR 2019*[4]

Note: For SHP of up to 10 MW except in the case of Brazil, Chile and Peru, where the local definition is used for the purpose of comparison with the previous editions of the *WSHPDR*.

Climate Change and Small Hydropower

The glacial stability of the mountainous regions in the western part of South America is affected by climate change. In the short term (the next 10 to 20 years), an initial increase in runoff could lead to a parallel increase in SHP plant capacity factors in the Andean region, but the loss of glacial cover risks making hydropower less viable in the long term by the end of the century. In the eastern part of South America, climate change projections indicate a decrease in rainfall and an increase in temperature during the peak rainfall season, combined with less precipitation during the dry season. The expected decreased runoff and an increase in seasonal flow variability threatens the viability of run-of-river hydropower projects.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Barriers to SHP development in **Argentina** include a lack of up-to-date studies of SHP potential, technical constraints on the addition of new capacities to the electricity grid and long-term impacts of climate change including the depletion of glaciers, which is expected to lead to reductions in runoff. At the same time, the country possessed a considerable undeveloped SHP capacity, an inventory of identified potential sites and a well-established SHP sector. Financing for future SHP projects is available through the country's RenovAr programme.

Bolivia has prioritized the development of large hydropower over SHP, and the country lacks a clear framework for the development of SHP projects and detailed data on potential sites. Low electricity prices in the country limit the attractiveness of SHP projects to private investors. Additionally, there has been a degree of resistance from local communities against hydropower projects. On the other hand, despite the lack of clear data, SHP potential in the country is believed to be considerable. Many rural communities could benefit from electrification delivered by off-grid SHP projects. Additionally, opportunities exist with regard to repair and refurbishment of existing plants.

Despite a very active SHP sector, obstacles to SHP development in **Brazil** include limited incentives for SHP relative to other RES, high construction and operating costs and strict environmental requirements fuelled in part by public scepticism about hydropower development in general. Overall, however, the outlook for the SHP sector in Brazil is positive as the country has extensive experience in SHP development and the sector is represented by an industry group of SHP developers. With a very significant SHP potential remaining untapped, particularly for SHP of up to 30 MW, the presence of incentives for SHP of below 5 MW and specific government targets for SHP expansion over the next decade can be expected to drive additional expansion of SHP capacities.

There are a number of factors complicating SHP development in **Chile**. These include a broad range of issues related to water use rights, lack of information and engagement with local communities on prospective and ongoing projects, unclear environmental standards and increasing water stress as a result of climate change. However, the country's undeveloped SHP potential remains one of the largest in the region. Chile has indicated its commitment to RES development and decarbonizing the economy, with SHP poised to play an important role in this process.

A major barrier to further SHP development in **Colombia** is the variability in generation from hydropower due to the effects of climate change, which is causing the country to reconsider its dependence on hydropower and prioritize the development of other RES. Additionally, institutional fragility and obstacles in negotiating with local communities and landowners can discourage investment in SHP, particularly in remote areas. The main enabler of SHP development in Colombia is the country's significant untapped SHP potential.

Similar to other countries in South America, the electricity sector development strategy of **Ecuador** has prioritized large hydropower plants over SHP. Additionally, despite the country's abundant undeveloped SHP potential, there is a lack of detailed data on technical and economic potential. At the same time, recent legislation on distributed generation and newly-proposed incentives for RES may provide a boost to SHP development in the country.

The main barrier to SHP development in **French Guiana** is significant seasonal variability of rainfall and runoff as a result of climate change, which poses a major challenge to stable hydropower generation in the country. Additional obstacles include administrative hurdles, high cost of electricity and difficulties with power transmission in remote parts of the country. Enablers of SHP development in the country include the planned partial closure of existing thermal power capacity, which is expected to act as a catalyst of RES development, as well as existing undeveloped SHP potential.

In **Guyana**, SHP development is hampered by a lack of detailed hydrological data, difficulties in providing grid connections and road access to project sites, and lack of local technical expertise. However, the rapid economic growth of Guyana over the last couple of decades, coupled with some recent momentum in the SHP sector including increased financing opportunities, may contribute to ongoing development of SHP in the country.

The main barrier to SHP development in **Paraguay** is the country's focus on large hydropower and the institutional structure underlying the current model of electricity generation in the country, which is heavily export-oriented. In addition, new policies have prioritized the development of RES other than hydropower. At the same time, the country has significant untapped SHP potential, and SHP could be employed to localize and increase the reliability of electricity supply in some areas suffering from high transmission losses.

Barriers to SHP development in **Peru** include the high initial cost of investment relative to thermal power, lack of human capacity for operation and maintenance of SHP plants, insufficient awareness among potential investor of the profitability of RES projects and issues with transportation infrastructure. Concerns over the potential environmental impact of SHP plants present an additional obstacle. Enablers include the country's extensive experience with hydropower and SHP in particular, abundant undeveloped SHP potential and several forms of support including long-term power purchase agreements, tax waivers and guaranteed purchase prices for electricity generated by SHP.

In **Suriname,** SHP development is hampered by high start-up costs, lack of funding and lack of local technical capacity in the SHP sector. The main potential driver of future SHP development in the country is the acute need of many rural settlements for stable electricity access.

The main barriers to SHP development in **Uruguay** are the country's focus on large hydropower, high costs of SHP projects relative to other RES, limited incentivization and socio-environmental restrictions. At the same time, abundant identified potential capacity and previous detailed studies of potential sites, in addition to a policy framework generally supportive of RES development, provide a solid base for future SHP development in the country.

In **Venezuela**, the main barrier to SHP development is the ongoing crisis in the electricity sector that has forced the Government to focus on large-scale projects. Additionally, data on potential sites as well as the state of existing plants is insufficient to promote development in the SHP sector. However, SHP projects could help promote decentralized generation and increase the stability of the electricity supply, particularly in the north-western part of the country, which is located farther away from existing hydropower plants and suffers from increased transmission losses.

Argentina

Raul Pablo Karpowicz, KWZ

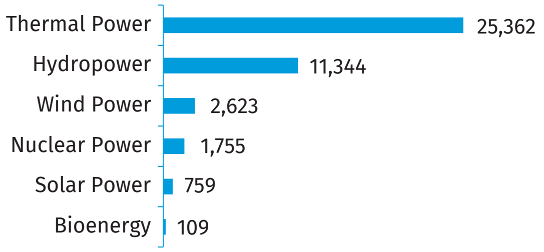
KEY FACTS

Population	45,377,000 (2020)[1]
Area	2,780,400 km^2[2]
Topography	The terrain comprises rich plains of the Pampas in the northern half, a flat to rolling plateau of Patagonia in the south and the rugged Andes along the western border. The highest point is Aconcagua, at 6,962 metres.[3]
Climate	Argentina is located within the subtropical-temperate zone. However, its extension between approximately 22° SL and 55° SL ensures great climatic diversity The north of the country has a warm and humid subtropical climate. Central Argentina has a temperate continental climate, with very hot summers and mild winters. The South has a subarctic climate and is directly influenced by the prevailing westerly winds. As the prevailing westerly winds lose their moisture and descend into Argentina, temperatures increase while humidity decreases. In the West, the Andes Mountain Range is a great determinant of the regional climate, since the high peaks from 40° SL and towards the north, together with the remoteness of the Atlantic, determine continental characteristics. January is the warmest month, while June and July are the coldest. The average annual temperatures range from 10 °C in July to up to 25 °C in January.[3,4]
Climate Change	Historically, in Argentina temperatures have risen by 0.5 °C since the beginning of the 20th century. During the latter half of the century, warming was felt in Patagonia with both maximum and minimum temperatures increasing in the region. The number and intensity of heatwaves have increased between 1960 and 2010. Precipitation has increased since the early 20th century, notably in the subtropical zones, albeit variable year-on-year. Under the most extreme climate change scenario, Argentina could see an increase of 3.5 °C by the end of the century compared to the 2014 levels.[5]
Rain Pattern	Rainfall is variable, depending on location and elevation. The north receives rain throughout the year with the annual average of approximately 750 mm. In central Argentina, the average annual rainfall varies between 1,000 mm in the east and 500 mm in the west towards the Andes. The south receives the least rainfall, with a low average of 200 mm. Towards the south, the mountain range is low and the ascent of the winds from the west produces precipitation on the Chilean side and over a narrow strip on the Argentinean side, and the winds subsequently lose their moisture by the time they reach the Patagonian plateau.[3,6]
Hydrology	The major rivers in Argentina include the Pilcomayo, Paraguay, Bermejo, Colorado, Río Negro, Salado, Uruguay and Paraná, the largest river in the country (15,000 m^3/s). The latter two flow together before meeting the Atlantic Ocean, forming the estuary of the Río de la Plata. Regionally important rivers are the Atuel and Mendoza in Mendoza province, the Chubut in Patagonia, the Río Grande in Jujuy and the San Francisco River in Salta. The provinces with the greatest small hydropower potential include San Juan, Mendoza, Rio Negro, Chubut and Santa Cruz.[3]

ELECTRICITY SECTOR OVERVIEW

At the end of 2020, the total installed capacity of Argentina was 41,952 MW.[7] The installed capacity of fossil fuel-powered thermal power plants (diesel or natural gas) was 25,362 MW. The installed capacity of hydropower amounted to 11,344 MW. Nuclear power accounted for 1,755 MW and wind power (2,623 MW), solar power (759 MW) and biomass (109 MW) made up the non-hydropower renewable sources (Figure 1).[7]

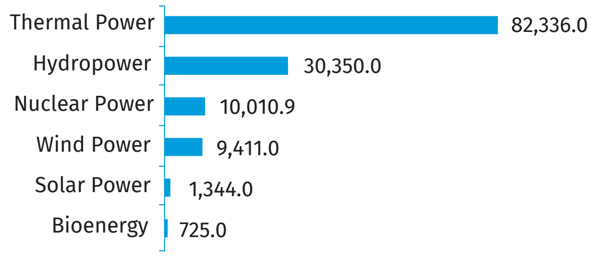
Figure 1. **Installed Electricity Capacity by Source in Argentina in 2020 (MW)**



Source: CAMMESA[7]

Total electricity generation in 2020, discounting imports, was 134,177 GWh (135,381 GWh including imports). The contribution of small hydropower SHP (below 50 MW) amounted to 1,257 GWh, whereas large hydropower contributed 29,093 GWh, totalling 30,350 GWh. Non-hydropower generation came from thermal power (82,336 GWh), nuclear power (10,011 GWh), solar power (1,344 GWh), wind power (9,411 GWh) and bioenergy (725 GWh) (Figure 2).[7]

Figure 2. **Annual Electricity Generation by Source in Argentina in 2020 (GWh)**



Source: CAMMESA[7]

During the last 15 years the share of hydropower in the total installed capacity of Argentina has decreased, mainly because thermal power, wind power and solar photovoltaic (PV) power are less time-intensive from project conception to operation. The decreasing international equipment prices in solar PV and excellent wind capacity factors in the Patagonia as well as promotion of renewable energy have supported this tendency. Moreover, construction of large hydropower plants in Argentina is complicated due to an unstable economic situation in the country and environmental concerns. Theoretically, the country has enough water resources to generate approximately 170,000 GWh annually.[7] However, so far it barely produces 20–25 per cent of that energy volume.[8]

Transactions between the different participants in the electricity industry are carried out through the Wholesale Electricity Market (WEM) controlled by the Wholesale Electricity Market Management Company (Compañía Administradora del Mercado Mayorista Eléctrico, CAMMESA), the administrator of the electricity market. The WEM is organized as a competitive market in which generators, distributors and certain large electricity users can buy and sell electricity at prices determined by supply and demand; others are allowed to enter into long-term electricity supply contracts. The WEM consists of:

- A term market where the quantities, prices and contractual conditions are agreed on directly between sellers and buyers according to specific resolutions, such as the "Term Market for Renewable Energies" (MAT ER), established by Resolution No. 281/2017 of the former Ministry of Energy and Mining;
- A spot market, where prices are established per hour based on the economic cost of production;
- A stabilized system of spot prices through seasonal prices, established every six months and designed to mitigate the volatility of spot prices for the purchase of electricity by distributors.[9]

The electricity is transported through the SADI (Argentina Interconnected System). There are public and private companies involved in the generation, transport and distribution of energy. Pampa Energía is one of the fast-growing private companies that is heavily involved in the renewable energy arena.[10] The National Electricity Regulatory Commission (ENRE) is an independent entity within the State Secretariat for Energy and is responsible for regulating the energy industry.

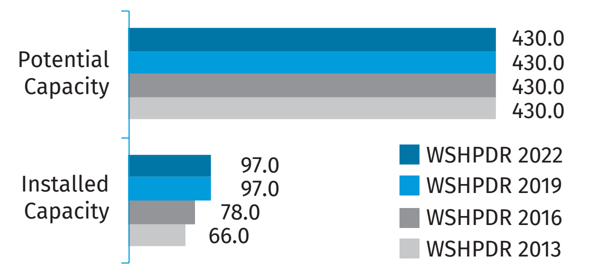
The large interconnection networks allow the transportation of energy flows at a regulated cost. However, transmission lines at medium and high voltage are not enough to satisfy new generation. This is a structural deficit to be overcome, as larger energy projects are unable to connect due to these transmission grid capacity constraints. Nonetheless, the country has had 100 per cent electrification since 2017.

Public electricity tariffs are regulated by the Government. As of March 2021, the household prices were 0.058 USD/kWh, while business prices were 0.039 USD/kWh.[11] Prices were frozen in 2019 following a period of high inflation that drastically impeded the country's economic growth and reduced consumer spending power. More recently in May 2019, the regulator announced that distribution firms Edenor and Edesur would introduce a 9 per cent tariff increase around the city of Buenos Aires to guarantee continuity in provision, with immediate effect.[12]

SMALL HYDROPOWER SECTOR OVERVIEW

In Argentina, SHP is classified as hydropower plants with an installed capacity of less than 50 MW. For the purposes of comparison with the previous editions of the *World Small Hydropower Development Report* (*WSHPDR*), the 10 MW definition will be used in this chapter. The current installed capacity of SHP plants of under 10 MW is 97 MW from 24 plants, thus there is no change from the *WSHPDR 2019* capacity levels (Figure 3, Table 1).[7] There are 43 SHP plants of a capacity of less than 50 MW, with a total of 510 MW of installed capacity.[6] There is no updated information on overall potential capacity since the previous editions of the *WSHPDR*.

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Argentina (MW)**



Source: CAMMESA,[7] *WSHPDR 2013*,[13] *WSHPDR 2016*,[14] *WSHPDR 2019*[15]

Note: Data for SHP up to 10 MW.

There is a great potential for SHP in Argentina. A national inventory of SHP facilities was conducted by the former Ministry of Energy and Mining has identified 116 potential projects, at different levels of development (see Table 3).[16] A plan for the dissemination of SHP has been proposed. Firstly, it will be necessary to conduct thorough impact studies of the hydrological, geological, geotechnical and environmental situation. Few studies have been conducted so far and there are numerous plants and facilities which require modernization. Secondly, it is also recommended to evaluate additional environmental benefits, the social cost of externalities as well as the supply of drinking water with the aim of including them in remuneration for potential investors and companies interested. In addition, ensuring that all provinces of Argentina accept and implement the distributed generation law may further enhance the development of SHP in the country.

Western areas of the country are very attractive for SHP development. Wind power is growing very fast because of the high-capacity factors in Patagonia (south of the country); however, the transmission lines capacity remains a limiting factor. Solar PV plants are being developed mainly in the north (Jujuy province). Several SHP projects are in planning at various stages (Table 2). However, the planning timelines have been drawn out over several years and the current status of these projects is difficult to determine. Table 3 presents a list of projects available for investment.

RENEWABLE ENERGY POLICY

By October 2015, Law No 27.191 was enacted (regulated by the necessity and urgency Decree No. 531/16), modifying Law No 26.190 to promote the use of renewable energy sources.[20,21] Among other measures, it was established that by 31 December 2025, 20 per cent of the total energy demand in Argentina must be covered with renewable energy sources. To achieve this objective, the GUs (large users) of the WEM and CAMMESA must cover 8 per cent of their demand with renewable sources as of 31 December 2017. This percentage is to be increased every two years until reaching the aforementioned objective. The contracts entered with GUs and GUDIs (large distribution users) cannot have an average price exceeding 113 USD/MWh.

Resolution No. 281/17 of the MEyM (former Ministry of Energy and Mining) issued in 2017 regulates the Term Market of Renewable Energies (MAT ER) regime. The resolution established the conditions for GUs of the WEM (Wholesale Electricity Market) and GUDIs to follow in relation to their obligation to meet their demand through renewable sources, whether through individual contracting in the MAT ER or by self-generation. Likewise, the conditions that generation projects must meet are regulated. In particular, the RENPER (Registry of Electric Power Generation Projects from Renewable Source) was created, in which such projects must be registered.[22]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

Currently, the legal umbrella for SHP is Law No. 27.191, which modifies Law No. 26.190 to promote the use of renewable energy sources.[23] CAMMESA controls the transactions of energy based on conditions or regulations, such as the contracts awarded in the RenovAr programme and contracts in the MAT EW market. Water use rights and permits, including environmental permits, are the jurisdiction of provinces. SHP plants whose energy production is not transported by the interconnected system are regulated by the provinces in accordance with the national laws. The Regulatory National Dam Safety Argentinian Authority (ORSEP) is the national entity responsible for regulating the safety dams in the country, including those used for hydropower generation.

The Ministry of Economy Energy Secretariat has a directorate directly involved in the promotion of SHP in the country, the National Directorate for Promotion (DNPROM). The objectives of the DNPROM include:

- Surveying the facilities in operation and out of service as well as those suitable for refurbishment and of public irrigation structures that can be equipped with generating units;
- Compilation, review and proposal of reformulating the provincial legal regimes of water, environment and energy, in agreement and collaboration with governments and provincial agencies;
- Analysis of the profitability of SHP in isolated markets, development of case studies and a roadmap of projects related (or not) to the Clean Development Mechanism;
- Identification and management of public and private financing lines for the execution of the technical and economically feasible works.

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

SHP is promoted by the Government's programme RenovAr, which called for bidders interested in investing, who then receive a payback from sales of energy during a period of up to 20 years. The RenovAr programme is controlled by the Ministry of Economy Energy Secretariat and promotes actions aiming to encourage large-scale investments in renewable energy projects. The RenovAr was launched in different stages, officially named rounds: Round 1, Round 1.5 and Round 2. The differences between these stages were the modifications in the available quotas for the different types of renewable sources and the adjustments of the referential prices. Referential prices depend on the energy source — wind power, solar PV, biomass or hydropower. The latest prices awarded during the second round were between 89 USD/MWh and 105 USD/MWh.[24] Nine projects were awarded in round 2, representing a total capacity of 21 MW (Table 4).[23]

Source: Ministry of Economy, Energy Secretariat[23]

Additionally, renewable energy projects can benefit from various incentives, including tax benefits (early VAT refund, accelerated amortization of income tax, exemptions from import duties, etc.), and the constitution of the Fund for the Development of Energy Renewables (FODER), which is destined, among other objectives, to grant loans, capital contributions, etc. to contribute to the financing of such projects.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

As a result of climate change, the Paraguay, Uruguay and Paraná Rivers have seen an increase in their mean flows as well as the frequency of extreme discharge events.[4] The glacial stability of the Andes Mountains is also affected by climate change as glacial melt puts at risk the balance of water provision for hydropower dams. The initial increase in runoff could increase plant capacity factors but make hydropower business models less viable in the long term.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Argentina has great SHP potential. Overall, hydropower is considered as an available and economical technology for national development in the long term, which, if appropriately planned, can serve multiple purposes, including tourism, water supply, flood control, irrigation, local development, etc. However, several barriers hinder further development of the SHP technology in the country, including the following:

- Extensive studies involving multiple jurisdictions with corresponding permits and environmental concerns delaying new projects;
- Slow development of the sector in recent years;
- Electricity grid constraints limiting new capacity additions;
- Long-term detrimental effects of climate change due to the depletion of glacial water resources;
- Limited information on potential capacity and sites.

The following points summarize the main enabling factors for further SHP development in the country that have been identified:

- A decent baseline of operational SHP projects as evidence of the viability of the technology in Argentina;
- An inventory of potential sites for development is available, albeit missing capacity-specific information;
- Potential short-term increase in plant capacity due to climate change effects and glacial melt;
- Availability of financing from the national RenovAr programme.

In this context, it appears critical to create new specific legal incentives that could facilitate SHP development, considering all its benefits that other renewable energy technologies cannot offer. Public-private solutions or refurbishment of old power plants could offer key opportunities for the development of the SHP sector.

Bolivia (Plurinational State of)

Cleber Romao Grisi, WHITEnergy Bolivia

KEY FACTS

Population	11,673,029 (est. 2020)[1]
Area	1,098,581 km^2 [2]
Topography	Bolivia is a landlocked country with geographic zones featuring great variations in altitude.[1,3,4] The Andean zone lies in the west of the country and covers approximately 28 per cent of the national territory. It is a mountainous zone formed by the Occidental, the Oriental, the Royal, the Cordillera Central and the Altiplano. The highest point is the Sahama peak at 6,542 metres; the average altitude in the Andean region is between 3,750 and 4,000 metres.[1,3,4] The Sub-Andean zone, commonly known as the Yungas and the Valles, consists of valleys of varying altitudes, with an average of 2,500 metres. The Eastern Plains, known as the Llanos, cover the tropical savannahs, the Amazonian forest, agricultural lands and the desert region of El Chaco. This zone occupies almost two-thirds of the national territory. The region has an average altitude of 400 metres and a minimum altitude of 90 metres at the Paraguay River.[1,3,4]
Climate	The Andean zone has a desert polar climate, with strong, cold winds and high solar radiation; temperatures range between a minimum of below 0 °C and a maximum of 20 °C. The Sub-Andean zone features a very humid and rainy climate, with the average temperature ranging between 15 °C and 25 °C. Finally, the average temperature in the Eastern Plains is approximately 30 °C.[1,3]
Climate Change	Since the year 2000, the country's average temperature has increased by 0.1 °C. It is expected that the average temperature will rise by 3.6–5.1 °C by the year 2100. The major effects of the rising average temperatures in Bolivia include the disappearance of glaciers on mountaintops (for example, the Chacaltaya Peak), a decrease in rainfall, a reduction of average humidity, an increase in the duration of periodic droughts, changes in the rainfall pattern and the increasing severity of flood events.[5,6,7]
Rain pattern	Bolivia has a tropical climate with average precipitation of 640 mm per year. The rainy season lasts from mid-October to March.[8,9] Rain is much more pronounced in the Sub-Andean zone and the Eastern Plains. Precipitation patterns in these zones vary from 2,000 mm per year in the north to 600 mm per year in the south. Precipitation is highest in the valleys, reaching up to 6,000 mm per year.[3,9] In the Andean zone, particularly on the Altiplano, it rains much less. Precipitation can be as low as 200 mm per year, except in the area surrounding the Titicaca Lake basin where precipitation can reach up to 1,000 mm per year.[3,9]
Hydrology	The most important rivers of Bolivia start in the Andes Mountains and descend across the valleys into the eastern tropical lands. The three main watersheds and river systems are: 1) the Amazon basin, which runs from the east to the west, composed mainly of the Madre de Dios, Orthon, Abuná, Beni, Yata, Mamore and Iténez (or Guaporé) Rivers. The Guaporé, the Mamoré, the Beni and the Madre de Dios cross the often-flooded northern savannah and tropical forests, all converging in the north-east to form the Madera River flowing into Brazil. 2) The Central or Lake basin, formed by Titicaca and Poopó Lakes, the Desaguadero River and large salt lakes Coipasa and Uyuni. Titicaca Lake is 222 km long and 113 km wide; with its surface at an altitude of 3,805 metres, it is the highest navigable lake in the world. The lake is drained to the south by the Desaguadero River, which empties into Poopó Lake. 3) The South or the La Plata River basin is composed mainly of the Paraguay, Pilcomayo and Bermejo Rivers, which cross the Chaco region to the south-east as they leave Bolivia to form the border between Paraguay and Argentina.[3,4]

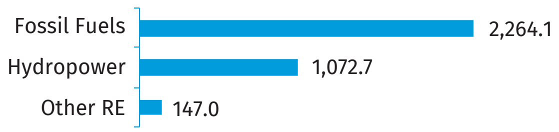
ELECTRICITY SECTOR OVERVIEW

The electricity sector of Bolivia includes the national grid, known as the National Interconnected System (SIN), several isolated networks, the wholesale market, the end consumers and the electricity authorities.[10,11]

In 2019, the total installed capacity in Bolivia was 3,483.8 MW and the total electricity generation amounted to 10,699.4 GWh, of which 89 per cent was supplied to the SIN and 11 per cent to the isolated networks.[10,12,13,14] The SIN covers the entire country except for the territory of Pando in the north.[10] In 2019, the total installed capacity of the SIN stood at 3,150.1 MW and electricity generation totalled 9,530.8 GWh. The maximum registered power demand of the end consumers amounted to 1,512.3 MW and the total electricity demand reached 9,242.2 GWh. The energy demand grew by 22 per cent relative to 2016 and by 3 per cent relative to 2018. There were 5,860.5 km of transmission lines, including 3,754.1 km at 230 kV, 1,892.2 km at 115 kV and 214.2 km at 69 kV.[10]

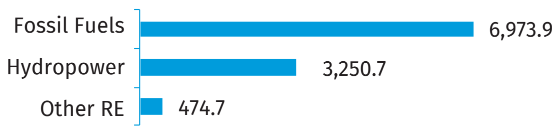
The major share of electricity in Bolivia in 2019 was produced by non-renewable thermal sources, mainly natural gas combustion and some diesel turbines, with an installed capacity of 2,264.1 MW (65 per cent of the total) and an annual generation of 6,973.9 GWh (65 per cent of the total), followed by hydropower with an installed capacity of 1,072.7 MW (31 per cent) and an annual generation of 3,250.7 GWh (30 per cent) and other renewable energy sources, including wind power, biomass and solar power, in total representing 147 MW of installed capacity (4 per cent) and a total annual generation of 474.7 GWh (4 per cent).[10] Figures 1 and 2 show the 2019 installed capacity and electricity generation, respectively, in Bolivia by source.

Figure 1. **Installed Electricity Capacity by Source in Bolivia in 2019 (MW)**



Source: CNDC,[10] AE[14]

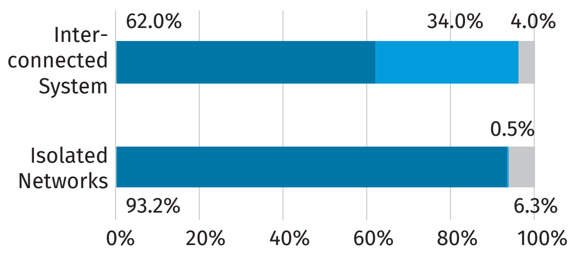
Figure 2. **Annual Electricity Generation by Source in Bolivia in 2019 (GWh)**



Source: CNDC,[10] AE[14]

In 2019, there were a total of 25 registered isolated networks in Bolivia. This represents a decrease from the number cited in the *World Small Hydropower Development Report (WSHPDR) 2019* (38 networks), which is due to the merging of some of the previously isolated networks with each other or with the national grid. Registered isolated networks use a combination of hydropower, solar power, biomass and thermal power (gas and diesel) as energy sources (Figure 3). These networks produced a total of 702.67 GWh of electricity in 2019.[14] Apart from the registered isolated networks, there are also non-registered isolated networks in many parts of the country. There is a lack of up-to-date and accurate data related to these non-registered networks; however, their combined installed capacity is estimated at 27.5 MW.[12,13,15]

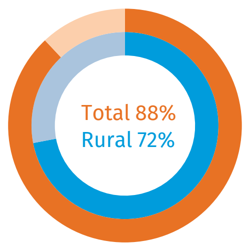
Figure 3. **Share of Installed Capacity of Electricity Networks by Energy Source in Bolivia in 2019 (%)**



Source: CNDC,[10] AE[14]

In 2019, the estimated rate of access of the population to electricity in Bolivia was 88 per cent, with urban coverage at 99 per cent and rural at 72 per cent (Figure 4).

Figure 4. **Electrification Rate in Bolivia in 2019 (%)**



Source: Ministry of Hydrocarbons and Energy[16]

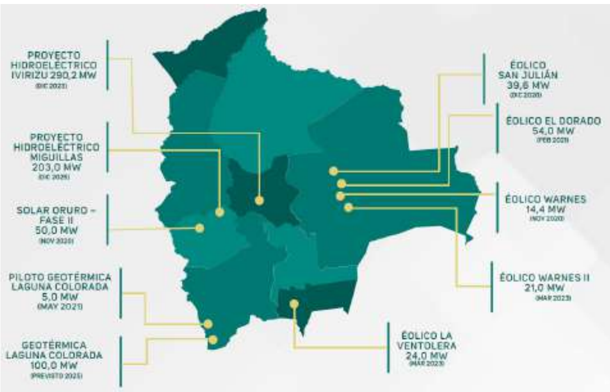
The government authorities and institutions that regulate the Bolivian electricity sector are the Ministry of Hydrocarbons and Energy, through its two vice ministries — Vice Ministry of Electricity and Alternative Energies and Vice Ministry of Energy High Technologies; the regulation and control authority, the Electricity and Nuclear Technology Supervision Authority (AE); the interconnected system administration, control and operation entity, the National Committee for Cargo Dispatch (CNDC); and the state-owned National Electricity Company (ENDE).[10,11,16]

Both public and private companies participate in electricity generation, transmission and distribution in Bolivia. The largest stakeholder is the state-owned corporation ENDE, which owns most of the generation facilities, transmission and distribution utilities across the country. In addition, ENDE is responsible for planning the growth of the electricity market and for the development of energy projects.[10,11,14,16]

In 2014, the Government issued a plan for the expansion of the electricity sector, which estimated that by 2022 electricity demand would reach 14,336 GWh/year, requiring a total installed capacity of 2,297 MW.[17] Approximately 53 per cent of this future demand was intended to be fulfilled by hydropower.[17] The current installed capacity of Bolivia has, thus, already surpassed the goal established in 2014 by a wide margin; however, demand and generation both remain below the established target.

Following the mandate of the country's constitution and electricity expansion plan, the Government of Bolivia has been developing the electricity sector by increasing the installed capacity, merging isolated networks with the national grid and expanding the transmission and distribution lines to increase access to electricity.[10,11,14,16] From 2014 to 2019, the installed capacity of the national grid increased from 1,695.8 MW to 3,150.1 MW, indicating a growth of 86 per cent. However, electricity generation during the same period increased by only 22 per cent, from 7,836.5 GWh in 2014 to 9,530.8 GWh in 2019.[10] Between 2014 and 2019, the following generation projects were completed: Misicuni hydropower plant (120 MW), San José hydropower plant I (55 MW) and II (69 MW), Oruro Phase 1 solar power plant (50 MW), Uyuni solar power plant (60.1 MW), Yunchará solar power plant (5 MW), Termoeléctrica del Sur thermal combined cycle plant (263.2 MW), Warnes thermal combined cycle plant (269.2 MW), Entre Ríos thermal combined cycle plant (272.8 MW), expansion of the Unagro biomass plant (14.2 MW) and the Aguaí biomass plant (6 MW). Additionally, a number of merged isolated networks supplied by diesel generators contributed to the SIN capacity expansion with a total of 5.4 MW.[16] As of early 2021, there were 10 renewable energy projects under construction as part of the SIN expansion, of which 493 MW belonged to hydropower, 50 MW to solar power, 105 MW to geothermal power and 153 MW to wind power sources distributed throughout the country (Figure 5).[16]

Figure 5. **Energy Projects under Construction in Bolivia**

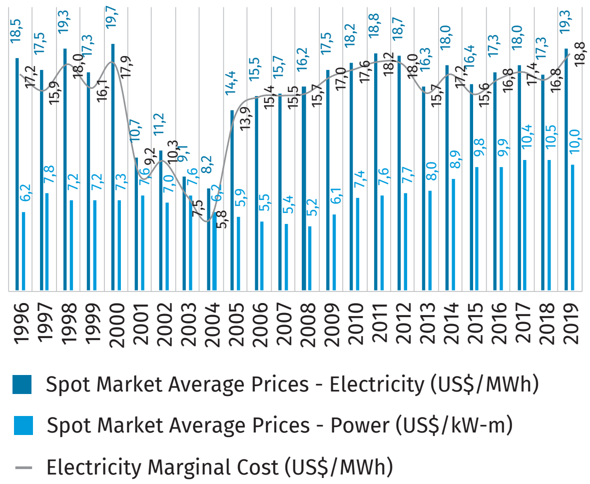


Source: Ministry of Hydrocarbons and Energy[16]

also responsible for the operation, safety and optimization of the national grid.[10,11,14]

For the commercial transactions in the SIN, on the spot market, the electricity sales are paid by the sum of two figures: the electricity produced and the power availability. The electricity sales price is a function of the generation marginal cost. This represents the electricity cost of the last unit required to generate the next kWh demanded by the system, affected by a factor that considers the losses at the node, where the electricity is delivered to the grid. The power availability price is the calculated cost related to the estimated investment and the fixed operation cost required to supply the demand plus a reserve in the long term to guarantee the supply of the future electricity demand.[10] In 2019, the average electricity marginal cost in the spot market was 18.84 USD/MWh and the corresponding average electricity sales price was 19.33 USD/MWh. The average power availability price per month was 10.0 USD/kW. Figure 6 shows the variation of electricity and power availability prices in the spot market since 1996.[10]

Figure 6. **Spot Market Marginal Cost and Sales Prices in Bolivia in 1996–2019**



Source: CNDC[10]

Despite fossil fuels being the predominant energy source, the electricity tariffs in Bolivia are among the lowest in South America. This is due to the subsidized gas and diesel prices for electricity production. The end users are classified into two groups: non-regulated and regulated consumers. If the demand of a single end user exceeds 1 MW, then the consumer belongs to the non-regulated group. Those in the non-regulated group can participate in the spot market as well as make power purchase agreements (PPA), which are to be first authorized by the competent authority. End users with a demand below 1 MW belong to the regulated group and their demand is attended to by the local electricity distribution utilities. The electricity transactions are held in the wholesale spot market administered by the CNDC, which is

SMALL HYDROPOWER SECTOR OVERVIEW AND POTENTIAL

The definition of small hydropower (SHP) in Bolivia is up to 5 MW; however, for the purposes of this Report, the standard definition of up to 10 MW will be used. Approximately 9 per cent of the electricity produced to supply the SIN comes from SHP plants (< 10 MW). These facilities belong to both private and public (ENDE) companies.[10]

In 2019, the installed capacity of SHP in Bolivia was 99.1 MW. Of this total, 12 plants with a total of 25 operational units and a combined capacity of 69.2 MW were connected to the national grid and one registered SHP plant of 1.2 MW capacity (Yocalla) was operating on an isolated network (Table 1).[14] The estimated electricity generation of the SHP plants connected to the national grid was 780.3 GWh in 2019.[10] Compared to the *WSHPDR 2019*, the installed capacity reported for SHP plants in Bolivia is lower by 53.7 MW (approximately 35 per cent) due to an earlier inclusion of hydropower plants with an installed capacity of below 30 MW and above the applicable SHP definition of up to 10 MW; which has been corrected for the current report. There is no reliable estimate of potential capacity for SHP as no specific studies related to SHP potential up to 10 MW are available; however, an overall potential capacity of approximately 200 MW for hydropower projects below 30 MW is estimated, which includes all currently installed hydropower plants of below 30 MW capacity (Figure 7).

Source: CNDC,[10] AE[14]

Note: Yocalla SHP plant located on isolated network; data on turbine type and plant type unconfirmed.

In addition to the officially registered SHP plants, there are SHP plants providing energy to non-registered isolated networks such as small villages or industrial sites (for example, mines). Some of these plants were constructed during the development of the mining industry back in the 19th century and many others were installed within the past 40 years to meet the demand of local communities. As of 2019, there were 68 identified SHP plants on non-registered isolated networks throughout the country with an estimated total installed capacity of 28.7 MW; however, precise data on these plants is difficult to provide.[12,13,15] Most of the identified power plants are out of service or in poor condition and could be eligible for refurbishment.

Bolivia has the potential to develop 39.9 GW of hydropower capacity. The most suitable region is the Amazon basin with a potential capacity of 34.2 GW, followed by the Plata River basin with 5.4 GW and the Andean basin (Altiplano) with 0.3 GW.[10,17,21,22] SHP potential in Bolivia has been estimated for projects of up to 30 MW capacity, as part of the Government's strategic plan for the development of alternative energy sources presented in 2014. The strategic plan includes the development of micro- (<500 kW), small- (500 kW–5 MW) and medium-scale (5–30 MW) hydropower projects.[23] The plan provides for approximately 30 MW of total hydropower capacity for grid connection and another 20 MW for isolated networks to be funded through both public and private investment.[23] Identification of potential sites to fulfil these targets is required.

As of 2019, construction of the El Cóndor SHP plant is in progress. This project has an estimated capacity of 1.47 MW and an average targeted annual generation of 9.85 GWh (Table 2). The project is funded by the Government and implemented by the state-owned company ENDE Valle Hermoso. The construction works started in 2019.[24]

RENEWABLE ENERGY POLICY

The Government has set the goal to change the country's energy mix, as of today dominated by gas units, to renewable energy sources, principally hydropower. An important reason to encourage hydropower projects is the country's enormous hydropower potential. The shift to renewable energy will also reduce natural gas use in local energy production and allow more natural gas to be instead exported to Brazil and Argentina. The export price for Bolivian gas is about seven times higher than the price established for the local market, which has been subsidized for electricity production.[10,11,17]

In 2014, the Government published the new Investment Promotion Law as well as Supreme Decree No. 2048 for remuneration of renewable energy projects and the promotion of investments in the electricity sector, in particular, hydropower, wind power, geothermal and solar power projects.[25] Therefore, today the political scene in Bolivia is becoming more suitable and attractive for both foreign and local investments in the electricity sector.[23]

Renewable energy projects, including run-of-river hydropower plants, will not be remunerated according to the actual electricity tariff system, which considers a combined payment for electricity produced and the capacity of available power. These projects will be paid for by energy production as stated in Supreme Decree No. 2048 of 2014.[25]

The energy tariffs for new projects are not defined yet, nor are financial mechanisms; regulations and investment frameworks are in the process of being implemented. Each project will have to negotiate and establish the electricity price through a purchase agreement according to the requirements of ENDE, the interests of the investor and the authorizations of AE. Some benefits offered to SHP projects may include:

- Exemption from taxes for importing equipment and construction;
- Subsidies coming from the Government's renewable energy fund;
- Guaranteed price from a mid- or long-term purchase agreement ensuring generation costs to be covered and an acceptable investment return rate;
- Stable tributary conditions for 10 years;
- Possibility to defer the aggregated value tax payment for five years from the beginning of the commercial operation date; and
- Some other benefits, including the exemption from paying the transmission and the grid administrator (CNDC) fees.[23]

The Government is also working on additional structures and rules to finance SHP and other renewable energy developments, such as by assigning incentives to local (department level) authorities for projects with an installed capacity of up to 2 MW and to municipalities or to indigenous authorities for projects with an installed capacity of up to 1 MW.[23]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

According to the studies performed since 2000, climate change in Bolivia is affected by El Niño and La Niña phenomena and CO_2 emissions, and has caused an increase in the average temperature of 0.1 °C, a decrease in rainfall and a reduction of average humidity.[6,7,25]

One of the major impacts of the climate crisis in Bolivia, with direct relevance to hydropower, is the retreat of glaciers. Over the past 40 years, more than 50 per cent of the country's glaciers have disappeared. This may result in a decrease in glacial meltwater feeding into streams and aquifers, particularly in the Andean region, implying that streams will depend more on rainfall. Rainfall has a linear relationship with stream flows, thus, the variation in rainfall will have the same effects in river streams.[5,6,7] As rainfall has also been decreasing and is expected to decrease further, studies predict that hydropower generation may reduce by 18–20 per cent by the year 2100.[7]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Bolivia is a country with potential for SHP development. There are many identified sites suitable for SHP facilities as well as existing plants in need of refurbishment.

The main challenges for SHP development in Bolivia are, but not limited to:

- Government priority and policies are to develop large hydropower to export electricity to neighbouring countries;
- Renewable energy development framework, rules and conditions have not been established yet;
- The low electricity prices are not very attractive for private investments;
- Poor quality of hydrological, climate and other statistical data required for hydropower studies, especially for rural areas;
- Complications associated with the establishment of a private company or development of a private hydropower project in terms of prices, competition and

public acceptance;
- Social situation in Bolivia, including roadblocks and protests, can interfere with project development, construction and further operations;
- Projects can be cancelled due to social resistance;
- Bureaucratic procedures, authorizations and paperwork to comply with the requirements often take longer than expected.

Some enabling factors for SHP development in Bolivia include:
- A hydrological and topographic environment favourable to hydropower development, with many rivers and streams offering more than 39.9 GW of total hydropower potential;
- A large number of small communities and electricity networks isolated from the national grid and in need of additional capacities; including multipurpose projects that provide a combination of irrigation, water supply and power production.
- Many existing SHP facilities are in need of refurbishment

Brazil

Geraldo Lúcio Tiago Filho, Camila Galhardo and Luiza Fortes Miranda, Brazilian National Reference Center for Small Hydropower Plants (CERPCH)

KEY FACTS

Population	211,755,692 (est. 2020) [1]
Area	8,510,346 km^2 [2]
Topography	The topography of Brazil is complex and includes a diversity of landscapes, but flat areas predominate. In the north lie the Amazon lowlands, which form the world's largest tropical rain forest. In the northernmost part of the country lie the Guiana Highlands, where the highest peak of Brazil, Pico da Neblina at 2,995.3 metres, is located. The Brazilian Highlands cover more than half of the national landmass including most of the central, eastern and southern parts of the country. The coastline is mainly represented by the Great Escarpment, which in the south-east is surmounted by mountain ranges.[3,4]
Climate	The climate is tropical in the central part of Brazil, temperate in the south and equatorial in the north. In the Amazonian region, average temperatures reach above 28 °C. The north-eastern region is humid, tropical and semi-arid with average temperatures between 20 °C and 28 °C. In the south-east, average annual temperatures vary between 19 °C and 24 °C. However, in the south, the coldest regions have average temperatures below 20 °C. During the winter month of June, the average temperature varies between 11 °C and 18 °C.[5,6]
Climate Change	Climate projections point to an increase in temperatures by 1 °C and 2.2 °C across Brazil by 2060, with the Amazon region experiencing increases of between 2 °C and 3 °C by 2050 and of as much as 5.3 °C by 2085, according to some estimates. The Amazon River delta is expected to experience a rise in sea levels of between 0.2 metres and 2 metres by 2100. Additional expected impacts of climate change in the Amazon region include the increased length of the dry season and heat waves as well as a decrease in precipitation.[7]
Rain Pattern	In the north of the country, specifically the Amazon region, the average annual precipitation varies from 1,700 mm to more than 3,000 mm in some locations. The north-eastern region experiences annual precipitation of between 300 mm and 2,000 mm. In the mid-west, precipitation is well spread and varies from 800 mm to 2,000 mm per year. In the south-east, rainfall ranges between annual averages of 800 mm in the northern part of the state of Minas Gerais and 2,500 mm on the coast of São Paulo. In the south, the precipitation varies from 1,300 mm per year to 2,100 mm per year.[8]
Hydrology	Administratively, the territory of Brazil is divided into 12 river basin districts, each containing one or more river basins. The Amazon River basin district comprises 80 per cent of all surface waters of the country.[9] The major rivers of this basin include the Amazon, Negro, Solimões, Madeira, Trombetas, Purus, Tapajós, Branco, Javari, Juruá, Xingu, Japurá and Iça. The Amazon River is the largest river in the world by volume and accounts for 20 per cent of all the fresh water flowing into the world's oceans. The Amazon River basin, is the largest in the world with an area of approximately 6,900,000 km^2, of which 3,800,000 km^2 are located on the territory of Brazil.[10]

ELECTRICITY SECTOR OVERVIEW

The total installed capacity in Brazil as of April 2021 was 177.3 GW, with hydropower accounting for 62 per cent of the total, conventional thermal power 16 per cent, wind power 10 per cent, biomass 9 per cent, solar power 2 per cent and nuclear power 1 per cent (Figure 1).[11]

In 2019, the electricity sector of Brazil generated a total of 626.3 TWh of electricity.[12] Hydropower contributed 64 per cent, conventional thermal power 13 per cent, wind power 9 per cent, biomass 8 per cent, nuclear power 3 per cent, solar power 1 per cent and other sources 2 per cent (Figure 2).[12]

According to The World Bank, Brazil reached 100 per cent access to electricity both in urban and rural areas by 2017.[13] However, in some remote regions far from transmission lines and urban areas, access to electricity remains precarious due to dependence on diesel generators and the complicated logistics of supplying the generators with fuel. The total electricity consumption in 2019 was 545.6 TWh (1 per cent more than in 2018). Of this, 36 per cent was consumed by the industrial sector, followed by the residential (26 per cent) and commercial (17 per cent) sectors. The other sectors represented less than 10 per cent each of the total consumption (Figure 3).[12]

Note: *Including own use.

The first hydropower plants were built in Brazil at the end of the 19th century, in order to meet the energy needs of the mining, textile and agricultural products processing industries. Until 1950, most of the hydropower plants in the country were small and predominantly located at waterfalls, allowing the direct use of hydropower. Later, in line with the centralized energy planning policies, many federal and state hydropower companies were created. This also induced the implementation of interconnected systems composed of large hydropower plants. Hydropower has been seen as a clean and efficient way to expand the energy capacity of Brazil. Additionally, because of the hydrological complementarity of the Brazilian regions, hydropower projects are well-suited for an interconnected energy system. There are currently 1,377 hydropower plants in Brazil, out of a total of 9,461 power plants of all types (Table 1).[11]

Table 1. **Power Plants in Brazil – May 2021**

Type	*Number*	*Installed capacity (MW)*
Hydropower > 30 MW	219	102,990.4
Hydropower 5–30 MW	425	5,506.4
Hydropower < 5 MW	723	818.2
Thermal power	3,087	44,397.2
Wind power	718	18,300.9
Nuclear power	2	1,990.0
Solar power	4,277	3,298.9
Wave power	1	0.05
Total	**9,452**	**177,302.1**

The process of privatization and unbundling of the electricity sector was started in 1994. The Government intended to change the model from a state-owned monopoly to private competition.[14] However, due to the lack of investment and the 2000 drought, which culminated in a severe crisis for the Brazilian electricity sector in 2001, the plan had to be postponed. The new regulatory framework, established between 2003 and 2004, made investment in renewable energy sources possible and laid down the foundation for the participation of public and private actors.[14] The energy market was standardized and adopted a hybrid model comprising a regulated part and a part of wholesale competitive trade. A recent public consultation (Public Consultation No. 33), which took place in July 2017, showed that most of the agents involved in the electricity sector would prefer the sector to be as free as possible.[15]

The Brazilian electricity sector is regulated through policies formulated by the Ministry of Mines and Energy (Ministério de Minas e Energia, MME) with the assistance of the National Council of Energy Policy (Conselho Nacional de Política Energética, CNPE) and the National Congress. The National Agency of Electric Energy (Agência Nacional de Energia Elétrica, ANEEL) is responsible for analyzing electricity sector resolutions to ensure the welfare of the society and the economy. ANEEL acts as a regulatory agency, while the National Energy System Operator (Operador Nacional do Sistema, ONS) is responsible for coordinating and supervising the centralized operation of the Brazilian interconnected energy system. The Committee for Monitoring the Electric Sector, also associated with the MME, was created to pertinently monitor and evaluate the continuity and security of the power supply across the country. There are also other players in the sector such as the Power Research Company (Empresa de Pesquisa Energética, EPE), which is also associated with the MME and whose role is to perform the necessary studies for planning the expansion of the electricity system. Another agent is the Chamber of Electric Energy Commercialization (Câmara de Comercialização de Energia Elétrica, CCEE), which handles negotiations on energy in the free market.[16]

Consumer tariffs are regulated by ANEEL, while the free-market prices are established through contracts. Electricity prices in Brazil vary according to the distribution company (i.e., the geographic region) and the end-user (residential, industrial, commercial, public service, etc.). Taking the average tariff applied in Brazil in 2020, the price decreased by approximately 1.6 per cent compared to 2019 and reached 0.503 BRL/kWh (0.0975 USD/kWh, based on the annual average dollar exchange rate) (Figure 4).[17]

Figure 4. **Average Annual Electricity Tariff in Brazil (BRL/MWh)**

SMALL HYDROPOWER SECTOR OVERVIEW

As of May 2021, there were 1,148 small hydropower (SHP) plants up to 30 MW in operation in Brazil with a total installed capacity of 6,324.6 MW. Of these, the total installed capacity of plants up to 10 MW was 1,608.2 MW.[11] The inventoried potential of SHP in Brazil is 15,765 MW from 1,752 sites, while recent studies point to another 20,000 MW of non-detailed potential for SHP.[18] The total inventoried potential (including operational plants as well as ongoing and planned projects) for plants up to 10 MW is 3,737.8 MW.[11] For the purposes of direct comparison with the previous editions of the *World Small Hydropower Development Report (WSHPDR)*, the up to 30 MW definition of SHP will be used in this chapter. Compared to the *WSHPDR 2019*, installed capacity increased by 11 per cent due to the introduction of new plants. The potential capacity changed based on a more accurate estimate of inventoried potential and new studies carried out on previously not studied rivers (Figure 5).[19] A list of recently commissioned SHP projects is displayed in Table 2.

Source: ANEEL[11]

The definition of SHP in Brazil has evolved over time. The first definition was set in 1982 and restricted SHP to 10 MW. However, this definition does not fit the present reality. As a result, ANEEL Resolution No. 673 of 2015 established a new definition of SHP as hydropower plants used for self-generation or independent electricity generation and with an installed capacity above 3 MW and below 30 MW.[22] Furthermore, the maximum reservoir area was limited to 13 km² (excluding the regular riverbed). In case of a reservoir area exceeding 13 km², the plant is still considered an SHP plant if this is at least a weekly regularized reservoir or if it has proven purposes other than electricity generation. Resolution No. 673 also states that hydropower projects below 3 MW have simpler implementation rules, only requiring the notification of ANEEL. This serves as an important incentive for SHP plants below 3 MW, although they are still required to abide by environmental and other state regulations.[23]

Law No. 13.360 of 17 November 2016 established a new definition of SHP as plants with an installed capacity from 5 MW to 30 MW.[23] However, the plants from 3 MW to 5 MW that were commissioned before the new law are still classified as SHP. Therefore, the actual installed capacity of all hydropower plants considered as SHP in the country exceeds the capacity of SHP according to the new definition. Furthermore, the definition of reservoir area of SHP plants as per ANEEL Resolution No. 673 is still being used. The Normative Resolution of ANEEL No. 765 of 2017 establishes the procedures for obtaining grants for hydropower projects between 5 MW and 50 MW that do not have all the characteristics of SHP plants listed above.[24] Finally, Normative Resolution No. 482 of 2012 regulating distributed generation, was updated by Normative Resolution No. 786 of 2017, which changed the maximum size limit for plants for distributed generation from 3 MW to 5 MW.[25,26] This means that more SHP plants can be considered as distributed generation plants and can enjoy the regulatory advantages available to this kind of generation, which were previously established by Resolution No. 673, including a simplified licensing process and access to the net metering tariff. Hydropower plants up to 5 MW (for distributed generation) are further classified as micro if their capacity is up to 75 kW and as mini if above 75 kW and below 5 MW.[25,26]

According to The Brazilian Ten-Year Plan for Energy Expansion 2029 (Plano Decenal de Expansão de Energia 2029, PDE 2029), the Government predicts that the installed capacity of SHP will reach 9,045 MW (4 per cent of total installed capacity) in 2029. As of 2021, the installed capacity of SHP in Brazil (6,324.6 MW) represented 3.6 per cent of total installed capacity and 93 per cent of the 2021 SHP installed capacity target of 6,787 MW.[27] This shows that the relative share of SHP in the country's energy mix is not expected to grow substantially. For comparison, the share of wind power is expected to rise from 11 per cent in January 2021 to 17 per cent in 2029, based on the assumption that the available incentives, such as tax exemptions, stay in place and continue to have a positive impact on the development of the source.[27] Several planned SHP projects are listed in Table 3.

SHP represents a renewable energy alternative which brings several benefits to the energy sector of Brazil, such as synergy with other sources as well as flexibility of operation and storage. Often, SHP also brings social and economic development to the areas where the plants are installed. In most cases, SHP entrepreneurs are required to invest in some local improvements as a mitigation measure for the environmental impact caused by the project. In particular, electrification through development of SHP in Brazil has been correlated with broad-based job creation and increases in labour productivity in the affected regions.[28,29] Although possible negative consequences of SHP development are reduced by the above measures, the general public in Brazil seems to associate the disadvantages of large hydropower with SHP as well. This has a significant negative impact on the public perception of SHP in the country and, therefore, on the prospects of SHP development.

RENEWABLE ENERGY POLICY

The Incentive Programme for Alternative Energy Sources (Programa de Incentivo às Fontes Alternativas, PROINFA) launched in 2002 was one of the major programmes to promote renewable energy sources in Brazil. The programme's primary focus was on biomass, wind power and SHP. This programme was similar to a feed-in tariff scheme, but was aimed at large-scale projects. Although PROINFA contributed to the diversification of the country's energy mix and the expansion of the share of some renewable energy sources, the prices of electricity generated from renewable energy sources remained high and the programme has been discontinued. The current mechanism to promote renewable energy sources in Brazil is through power auctions. Specific auctions are offered for a restricted group of energy sources, serving as an incentive for large-scale projects. Additionally, the net metering model was chosen for on-site generation, benefiting mainly the solar photovoltaics market.

In the last few years, wind power projects have been showing lower prices in the auctions and the construction and operating costs of SHP in Brazil have been higher than those of other energy sources. Besides, SHP electromechanical equipment is expensive and does not receive tax exemptions as does wind power and solar power equipment (e.g., the tax on circulation of goods and services). As a result of the balance of relative costs and incentives benefitting primarily large projects and non-hydropower renewable energy sources, SHP has lately been losing its share of the energy mix to other renewable sources. The Ten-Year Energy Expansion Plan 2029 (PDE 2029) of Brazil shows that SHP projects contracted as of 2019 were to account for only 6 per cent of the total power generation capacity to be commissioned in 2020, less than 8 per cent in 2021, 11 per cent in 2022, 0.2 per cent in 2023 and 2 per cent in 2024. Considering the entire period from 2020 to 2029, SHP represents only 4 per cent of the total contracted capacity, while wind power and solar photovoltaics represent 25 per cent and 10 per cent, respectively (Figure 6).[27] Although these data demonstrate that currently solar and wind power are growing faster than SHP, the PDE 2029 also indicates a wide range of SHP projects not yet developed that may be important for the energy expansion.

Figure 6. **Contracted Capacity Expansion in Brazil until 2029**

	2020	2021	2022	2023	2024	2025	2026	2027

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

The current environmental licensing process for SHP presents some barriers for development. According to the resolution CONAMA 01/86, power plants above 10 MW, regardless of the energy source, are considered as potential sources of negative environmental impact.[30] SHP projects between 10 MW and 30 MW therefore require an Environmental Impact Assessment (Estudo de Impacto Ambiental, EIA) and an Environmental Impact Report (Relatório de Impacto Ambiental, RIMA).

SHP projects between 3 MW and 10 MW, however, are only required to prepare a Simplified Environmental Report (Relatório Ambiental Simplificado, RAS). Hydropower plants below 3 MW have to go through an even less rigorous process of environmental licensing. On the other hand, SHP projects of this size are generally considered expensive and unattractive to investors. It should be noted that the limit of 3 MW set by the Environmental Law is lower than the 5 MW maximum capacity limit of SHP plants for distributed generation established by the ANEEL Normative Resolution No. 786. This is due to the fact that in Brazil environmental laws are treated separately from the laws on incentives for energy sources. Overall, the environmental licensing process for wind power and solar photovoltaic projects is faster and simpler than for SHP, serving as another incentive for these two renewable energy sources to the detriment of SHP.

Nonetheless, there are additional instruments of support for SHP as well. The key ones include:

- Free access to the transmission and distribution networks;

- Discount of at least 50 per cent on the tariffs for using the transmission and distribution systems;
- Exemption from the tax on land use for inundation;
- Incentives for distributed generation (plants up to 5 MW);
- Energy Reallocation Mechanism (MRE), in which SHP plants can participate optionally.

Despite the huge hydropower potential available in Brazil and the extensive national experience in hydropower generation, the current policies and financial mechanisms do not seem to provide an adequate market for the expansion of SHP. In contrast, wind power and solar photovoltaic power have recently been the main focus of policies promoting the expansion of renewable energy sources, with remarkable results. In the short term no changes to this scenario are expected. The stabilization of the relatively new renewable energy sources (solar photovoltaic power and wind power) in the national market is likely required in order for more competitive conditions for the expansion of the SHP plants to emerge.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

According to several studies published as part of the 2015 report "Scenarios and Alternatives for Adaption to Climate Change", climate change is expected to have severe impacts on the operation of existing hydropower plants in Brazil and the viability of planned projects. In particular, river flow to the country's four largest hydropower plants (Itaipu, Furnas, Sobradinho and Tucuruí) is expected to decrease by 38-57 per cent by 2040. The flow of the Xingu River in Amazonia feeding into the Bel Monte hydropower plant, currently nearing completion, is expected to decrease by between 25 and 55 per cent. This threatens the viability of the project, which is already expected to operate below full capacity due to seasonal flow variability.[31]

The Amazon region is expected to be hit particularly hard by climate change due to ongoing deforestation. A recent study of the climate change impacts on hydropower for the period 2026–2045 relative to the baseline period 1986-2005 in the Tapajós basin, much of which is run-of-river and highly sensitive to seasonal flow variability, projected a loss in generation of 312-430 GWh per month during the dry season. It also suggests a delay in the peak generation period by 22–29 days as well as an increase in interannual generation variability from 548 GWh to 713–926 GWh due to the combined effects of deforestation and climate change. The study additionally underlines that smaller hydropower projects are less prone to large-scale miscalculations of expected capacity in conditions of climate uncertainty.[32]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

SHP projects are currently in a disadvantaged position in Brazil in relation to other renewable energy sources, mainly wind power, which receives more incentives. The key barriers to SHP development include:

- Limited incentives compared to other renewable energy sources, which makes SHP projects less competitive;
- Strict requirements for the environmental licensing process for plants between 10 MW and 30 MW;
- High cost of constructing and operating SHP plants in comparison to other renewable energy sources such as wind and solar power in the context of Brazil;
- The costs of civil construction and electromechanical equipment are elevated and are not covered by tax exemptions;
- A generally negative public perception of all hydropower, mainly due to campaigns against large hydropower plants.

Factors enabling the development of SHP in Brazil include:

- A long history of hydropower development;
- Abundant unrealized SHP potential;
- Regulatory and licensing incentives for SHP below 5 MW, especially for SHP below 3 MW, and discounts/exemptions in the case of certain fees and taxes.

Chile

Patrick Furrer, Jorge Saavedra and Patricio Muñoz, AFRY Chile

KEY FACTS

Population	19,116,209 (2020)[1]
Area	756,100 km² (continental territory), 2,006,096 km² (continental, Antarctic and insular)[2]
Topography	Continental Chile is characterized as mountainous, with no more than 20 per cent of flat surface. The three main features of the relief of continental Chile are the Andes Mountains to the east, the coastal range to the west and the intermediate depression between the two mountain ranges. The highest peak is the Ojos del Salado at 6,893 metres in elevation. Between continental and southern Chile there is a submerged mountain range whose highest peaks emerge to form islands, eventually reaching the north-eastern tip of the Antarctic peninsula. Rapa Nui Island (Easter Island) presents a relief characterised by plains and volcanoes.[2,3]
Climate	Chile has a variety of climates: desert, Mediterranean steppe, warm temperature rainy, temperate rainy, maritime rainy, cold steppe, tundra and polar (from north to south). In the Andes, highland climate prevails and on its high peaks, icy weather. Rapa Nui has a subtropical climate with oceanic influence characteristics. Temperatures vary depending on the region; in the north, daily averages range from 12 to 23 °C. The central region average daytime temperatures range from 9 to 21 °C depending on the time of year, while in the south, average daily temperatures range from 2 to 16.8 °C.[2,4]
Climate Change	As a consequence of climate change, several studies have projected a significant decrease in mean monthly flows between the Region of Coquimbo and Region of Los Lagos (from 30° to 42° South) and an increase in the elevation of the zero isotherm, which implies a reduction of the water storage of nivo and nivo-pluvial basins as well as an increase in the risk of flood and landslide events.[5]
Rain Pattern	Rainfall varies in amount and distribution across the territory and increases towards the south. In the far north, the average annual rainfall is less than 1 mm, while at the southern tip it can reach 5,000 mm or more.[2]
Hydrology	As a result of the relief and the narrowness of the territory, the rivers are short, with steep slopes, low-flow, torrential and are unsuitable for navigation, but have great hydropower potential. The northern rivers are fed by snow thawing, the central ones have a mixed feeding, the southern ones by rainfall and the austral ones have mixed regimes, fed by rain and thawing glaciers. The longest river is the Lao river of 440 km, spanning the Andean mountain range and the Atacama desert. It has several main tributaries: the Salado River, the San Salvador River and the San Pedro de Inacaliri River. The next longest river is the Bío-Bío River, stretching 380 km from lakes Icalma and Galleutué, through the Andean valley. Both the Lao and the Bío-Bío rivers drain into the Pacific Ocean.[26]

ELECTRICITY SECTOR OVERVIEW

In October 2021, the total installed generating capacity of Chile was 26,653 MW (Figure 1), of which 99 per cent corresponded to the National Electrical System (SEN).[7] Hydropower is the most important source of electricity in Chile, making up 27 per cent of the total installed capacity. The total electricity generated in 2020 was 70,828 GWh (Figure 2).[8] There is a noticeable trend towards an increase in renewable energy generation, mainly in wind and solar power. As a result of the Paris agreement commitments by the government of Chile, there is a plan to decarbonize the energy mix; currently, there is an agreement to shut down 11 coal power plants by 2024, which represents 1,731 MW and 31 per cent of the total capacity of coal power plants.[9] An even more ambitious plan for accelerated decarbonization is also under discussion, but is not yet approved because of the possible marginal cost increases this would bring.

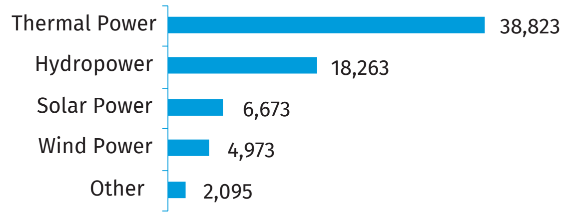
Figure 2. **Annual Electricity Generation by Source in Chile in 2020 (GWh)**



Source: NCE[8]

In the 1970s began the privatization and segmentation of the Chilean electricity market, starting with the distribution segment (originally owned by the Chilean National Electricity Company, ENDESA), followed by the generation and transmission segments, which were privatized and afterwards separated in the mid-1990s. Generation, transmission and distribution are unbundled horizontally. The sectors are, however, integrated vertically. Electricity system prices follow a marginalist approach and there are nodal prices given the grid constraints. Until 2005, the generation segment was dominated by three national companies, Enel (formerly ENDESA Chile), AES Gener (formerly GENER) and Colbún. The situation has changed substantially with the appearance of other competitors (medium- and small-sized players) with more than 400 generation companies currently active in the Chilean energy market.

The largest electrical system is the National Electrical System (SEN), which is the interconnection of the previous North Interconnected System (SING) and the Central Interconnected System (SIC). SEN serves approximately 98 per cent of the country's population. Other smaller networks are the Aysén System (SEA), Los Lagos generating unit and Magallanes System (SEM).

The transmission system can transport electricity from generating plants located throughout the country to distribution companies' substations and industrial consumers. The voltage levels in lines are between 23 kV and 500 kV, at a nominal frequency of 50 Hz. Transmission is dominated by four historical major players — TRANSELEC, ENGIE (Suez, E-CL), TRANSNET (CGE), ENEL (Chilectra) — as well as one new player INTERCHILE since the construction of the 500 kV system. At the moment of writing of this chapter, there was a bid for a HVDC line of ±600 kV between the Kimal and Lo Aguirre substations, which will improve the transport of electricity between the north and the central system of Chile. In terms of regional interconnections, an interconnection exists between the north of the country and Salta province in Argentina. The line has a length of 408 kilometres, 345 kV of rated voltage and is connected between the substations of Andes and Cobos (both owned by AES). According to the National Electrical Coordinator (CEN), the line is still awaiting approval and consequently there is no power flow registered for the moment.

The distribution system is principally in the hands of four companies: ENEL, CGE, Chilquinta and SAESA. The distribution system, consisting of lines, substations and equipment, is established in two voltage ranges (medium and low voltage). In the low voltage range, there are three rated voltages defined by the Chilean regulations. It is usual to use 380 V and 220 V in three-phase and single-phase installations, respectively:

- Medium voltage (Line-Line): 2, 4, 3.3, 4.16, 6.6, 12, 13.2, 13.8, 15 and 23 kV;
- Low voltage (Line-Line): 380, 480, 660 V;
- Low voltage (Line-Neutral): 220, 277, 380 V.[11]

As established by the General Services Law, the main bodies involved in regulating the electricity market are:

- Ministry of Energy: the public agency responsible for developing and coordinating the plans, policies and standards for the proper functioning and development of the energy sector, ensuring compliance and advising the Government on all matters related to energy;
- National Commission Energy: a public and decentralized body, with its own assets and full capacity to acquire and exercise rights and obligations. Its function is to analyze prices, tariffs and technical standards to which energy production, generation, transmission and distribution companies must adhere in order to have a sufficient, safe and quality service, compatible with the most economical operation;
- Electricity and Fuel Superintendence (SEC): the public agency responsible for overseeing the energy market, in order to have safe and quality products and services, as well as supervising compliance with electrical regulations in the country;
- National Electrical Coordinator (CEN): an independent body responsible for ensuring the security of the service in the electrical system, guaranteeing the most economical operation for all system installations, and planning the development of the transmission system. Additionally, it adopts the pertinent measures to monitor the chain of payments of the economic transfers subject to their coordination, guaranteeing their continuity;
- Panel of experts: a body created by law, with limited competence, made up of professional experts, whose function is to pronounce, by means of rulings with binding effect, on those discrepancies that occur in relation to the matters indicated in the General Law of Electrical Services (studies, tariffs, plans, etc.), and in other laws on energy matters;
- Ministry of Environment: the body that grants the approval of the environmental impact studies for projects in the sector;
- Municipalities: they oversee the issue of permits for the use of public assets.[9,12,13,14,15,16,17]

The average sale price of electricity (average node price in SEN) in December 2020 was 58.56 CLP/kWh (42.16 USD/MWh).[18] This value, however, does not consider the costs of distribution or the charge for the use of the national transmission system.

SMALL HYDROPOWER SECTOR OVERVIEW

Chilean Law No. 20.257 defines a small hydropower (SHP) plant as a hydropower plant with a maximum installed capacity of below 20 MW.[19] SHP is considered as a form of non-conventional renewable Energy (ERNC). The Renewable Energy and Energy Efficiency Programme of the Ministry of Energy classifies hydropower into micro-, mini- and small hydropower (Table 1).

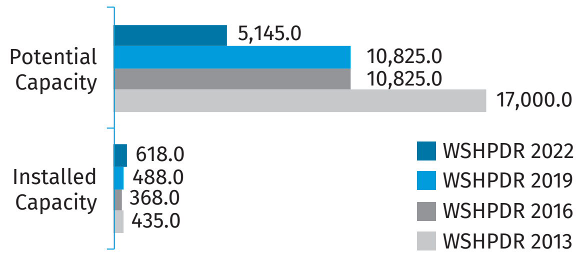
Table 1. **Classification of Small Hydropower in Chile**

Category	*Installed capacity*
Micro	5 kW–100 kW
Mini	100 kW–1 MW
Small	1 MW–20 MW

Source: Ministry of Energy [20]

The available capacity of SHP up to 20 MW as of January 2021 was 618 MW, distributed among 130 plants (Table 2). For SHP up to 10 MW, the installed capacity was 304 MW from 110 plants.[21] In comparison to data from the *World Small Hydropower Development Report (WSHPDR)* 2019, installed capacity has increased by almost 27 per cent (Figure 3). Conversely, the estimated potential has decreased due to new data made available, based on improved analytical methods and reflecting shrinking water availability in the country.[22] Additionally, in 2020 there were 77 MW of SHP under construction and 779 MW of SHP project with an Environmental Qualification Resolution (RCA), meaning that they had a permission to start SHP construction.[23]

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Chile (MW)**



Source: NEC,[16] Ministry of Energy, General Directorate of Water & University of Chile,[21] *WSHPDR 2013*,[24] *WSHPDR 2016*,[25] *WSHPDR 2019*[26]

Note: Data for SHP up to 20 MW.

The increase in the installed capacity of SHP was mainly due to regulatory changes in Decree 244, which regulates small, distributed power plants, referred to as PMG(D)s (Pequeños Medios de Generación, Distribuida) in Chile. It has simplified the processing of projects of less than 9 MW connected to the distribution network, particularly for projects under 1.5 MW that have no significant impact on the grid (known as INS in Chile). INS projects allow avoiding some electrical studies and steps to follow for the connection, which helps avoid important costs in the processing of the projects.[27]

The estimated SHP undeveloped potential up to 10 MW is equivalent to 2,691 MW and for SHP up to 20 MW is 4,527 MW (Figure 4). The most promising rivers are the Biobio (550 MW and 1,002 MW), Bueno (416 MW and 561 MW) and Tolten (292 MW and 526 MW).[17] This corresponds to the technical potential, which considers the Rights of Use of Non-Consumptive Water for installed power greater than 0.1 MW and plant factors greater than 0.5. This does not consider the potential in the southern part of the country (Aysén region) due to environmental restriction.[28] For SHP up to 10 MW, the total technical potential (including developed capacity) was estimated at 2,995 MW and for hydropower plants up to 20 MW at 5,145 MW.[17] An additional potential associated with reservoirs used for irrigation works was studied in 2007 for Rights of Use of Consumptive Water and is estimated at 866 MW. Of the known potential, 558 MW of capacity has less than 20 MW and flows above 4 m³/s.[29] Planned projects on these sites can be seen in Table 3.

RENEWABLE ENERGY POLICY

In 2016, the Ministry of Energy finished a participative process for the elaboration of a long-term energy policy called Energía 2050, which included the participation of different actors from the Government, industry, general public and universities.[31] This process concluded with the Roadmap 2050 and the 2050 Energy Policy.[32,33] These documents are based on four main objectives, including generating 60 per cent of energy from renewable sources by 2035 and 70 per cent by 2050.

In 2018, the Ministry of Energy published Energy Route 2018–2022, a roadmap for the four years of the new Government with seven lines of action: energy modernization (regulation and institutions), socialization of the projects, energy sector development, grid diversification with local low-emission energy, efficiency and electrification of transport, residential and industrial sector energy efficiency and energy education and capacity building.[34] Achievements include time reduction in the environmental approval process and the elaboration of a master plan for decommissioning or reconversion of coal power plants.

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

Ministry of Economy Decree 244 regulates the mini- and small hydropower sector, which belongs to the category of non-conventional renewable energy (ERNC) generators along with geothermal power, wind power, solar power, biomass and co-generation (Table 5).[9]

Law 19.940 includes the fee for small ERNC generators access to the transmission system and regulates the cost for the connection of small distributed ERNC generators to the distribution systems. Law 20.018 requires that energy generators provide at least 5 per cent of their energy through sustainable means or purchase the equivalent from renewable sources. This percentage is set to rise to 10 per cent by 2024.

Currently, a controversial amendment of the Chilean Water Code is under discussion in the National Congress.[35] The amendment project aims to modify the concept of water rights in order to: limit their exercise; make them temporary (20 or 30 years, with the possibility of renewal); limit the exercise of water rights in the event of scarcity situations; establish a “use it or lose it” clause; facilitate the Government’s intervention into hydrological areas and reform the non-use fee payment.

Law 19.300 on the general bases of environment requires that every energy generation plant with a capacity larger than 3 MW and a transmission line with voltage greater than or equal to 23 kV together with its substations must enter the system of environmental impact evaluation (SEIA). Projects that enter the SEIA must present an Environmental Impact Declaration, unless their impacts significantly change or intervene in some aspects defined in the law (population health, renewable natural resources, community resettlement and landscape value). In such cases, a full Environmental Impact Evaluation must be presented. In general, SHP projects present an Environmental Impact Declaration.

Law 20,698 was published in 2013 with the main goal of extending the energy mix by incorporating ERNC generation projects. This law set new goals for ERNC generation, changing the target share from 10 per cent by 2024 to 20 percent by 2025. Also, the Ministry of Energy has to make public tenders for annual blocks of energy provided by ERNC sources.

In 2016, Law 20,936 creating a new electric transmission system and an independent coordination agency of the national electric system was published. The main objectives of this law were to increase competition in the electric market, remove entry barriers to the energy generation market and boost the development of ERNC.

In 2016, the environmental evaluation services published a methodological manual for the calculation of the ecological flow. This is now used to define an independent ecological flow that prevails over the water right ecological flow. Although, this is only a guide, it is used as part of the regulation.

COST OF SMALL HYDROPOWER DEVELOPMENT

The development of SHP projects must consider different factors, such as water rights availability, environmental impacts, access roads, hydrological and geotechnical conditions, which are specific to the project location. The cost of SHP development is highly dependent on the project's location.[36]

Based on information provided by developers of generation projects, the National Commission of Energy has estimated the average development cost of run-of-river SHP plants (up to 20 MW) to be 3,263 USD/kW. The average variable cost depending on energy generation is estimated at 1.3 USD/MWh and the operational and maintenance cost non-related to energy generation is 1 per cent of the total expenditure. The total time of construction was estimated as three years.[32]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

In Chile, state financial mechanisms are provided mainly by the Corporation of Production Development (CORFO) and do not target specifically SHP but ERCN projects in general. CORFO created a special credit scheme to finance investment into construction, operation and commissioning of ERCN projects, with a maximum financing amount of USD 15 million.[37] In 2020, as a measure to mitigate the economic effects of the Covid-19 crisis, CORFO created a Green Credit to boost ERCN projects, energy efficiency and circular economy, with a maximum financing amount of USD 7 million for ERCN generation projects.[38]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Chile is highly vulnerable to climate change and meets most of the nine vulnerability criteria set by the United Nations Framework Convention on Climate Change (UNFCCC). Hydropower generation potential is expected to decrease by 11 per cent between 2011 and 2040 and by 22 per cent between 2071 and 2099 under the emission scenario A2 and by 10 and 16 per cent for the same periods, respectively, under the emission scenario B2.[3]

One measure to mitigate the effects of climate change on SHP is to add more flexibility by incorporating new technologies, such as using lithium-ion batteries to store energy. An example of this is the Virtual Dam initiative of AES Gener that installed batteries providing 10 MW for five hours at the run-of-river plant Alfalfal I (178 MW).[39] This initiative could be replicated at a smaller scale for SHP plants.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Chile has abundant energy resources and has made some effort in order to promote the development of renewable energy technologies, including SHP. However, there are barriers to their development and implementation. Regarding SHP, there are social, institutional and technical barriers, including the following:

- Ownership of water: Hydropower potential is not necessarily perceived as a natural condition of the water resource;
- Use of water: Competition for multiple uses in the river basins, in particular, with other productive uses, conservation and tourism;
- Asymmetry of information: Lack of information and good communication between the community and the developers generates mistrust;
- Balance of cost, risks and benefits: Lack of information within the communities about the cost, potential risks and real benefits associated with SHP projects generates the sensation of being robbed of their resources. The communities see only the external cost and usually overestimate the potential risks and revenues for the developer;
- The public at large feels left out of the planning of hydropower development, in particular, in areas with indigenous population;
- Absence of unified criteria of environmental impact assessment for SHP;
- A long approval process for the environmental and construction permits;
- Water rights can be monopolized;
- Ecological flow included in the water right is not considered in the environmental approval, a new ecological flow has to be defined;
- The water rights legal constitution is under modification;
- Normally, SHP development takes place far from the transmission lines, so that the project developers have to invest in the lines as well, which often makes projects unfeasible;
- Because of climate change it is expected that hydropower potential will decrease by 11–22 per cent;
- The central part of Chile has faced a mega-drought from 2010 to the present with mean rainfall deficits of 20–40 per cent;
- Increasing water stress due to climate change.

The following points summarize the main enablers for SHP development that have been identified:

- Due to its geography and climate, Chile has a high hydropower potential, a large part of which remains undeveloped;
- Aiming to reduce greenhouse gas emissions, several

state initiatives and policies have been or will be generated to boost renewable energy generation, including SHP. There is an ongoing decarbonization plan that has as goal to completely remove coal-fired thermal power plants from the energy mix by 2040. This policy could pose an opportunity for SHP because the shutdown of thermal power plants entails a reduction in baseload production, which could be provided for by SHP.

Colombia

Alexandra Planas Marti, Inter-American Development Bank

KEY FACTS

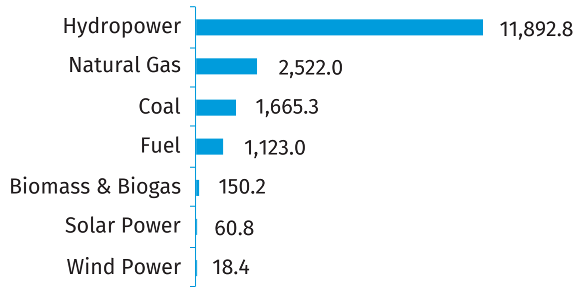
Population	48,258,494 (2018)[1]
Area	1,141,748 km² [2]
Topography	Colombia is situated in the northern part of South America and has a coastline on both the Pacific Ocean and the Caribbean Sea. The Andes Mountain Range crosses the western and central parts of the country, and the highest point in the country is the Sierra Nevada de Santa Marta (5,775 metres).[2] On the contrary, the eastern region of the country is characterized by extensive plains.
Climate	The climate of Colombia is shaped by its varied topography. The average temperature in the Pacific region is 26-28 °C, in the Orinoco region 24-28 °C, in the Amazonian 24-26 °C region and over 26 °C in the Caribbean region. At the same time, the average temperature in the Andean region varies between 8 °C and 24 °C.[3,4]
Climate Change	Even though Colombia emits 0.46 per cent of global greenhouse gas emissions, the country is highly vulnerable to certain effects of climate change such as floods, changes in water resources and rain patterns, desertification of productive soils and health issues like malaria and dengue fever.[5]
Rain Pattern	The highest average precipitation level is found in the Pacific region, where most municipalities receive between 4,000 mm and 9,000 mm of rainfall. However, some municipalities can receive more than 11,000 mm.6 High average precipitation can also be found in the Amazonian region, between 3,000 mm and 4,000 mm.6 The Orinoco and Caribbean regions have varied rain patterns, receiving between 1,000 mm and 4,000 mm of rainfall. Meanwhile, most municipalities in the Caribbean region receive less than 1,500 mm of rainfall per year.6 The Caribbean, Andean and Orinoco regions experience dry seasons from the last months of the year until March, when the wet season begins. On the other hand, the Pacific and Amazonian regions receive precipitation throughout the year.[7]
Hydrology	The hydrology of Colombia is characterized by the presence of wide and fast-flowing rivers (Magdalena, Causa, Amazonas, Putumayo, Caquetá and Guaviare, among others). This explains the country's hydropower potential as well as its vulnerability to climate change effects.

ELECTRICITY SECTOR OVERVIEW

As of December 2020, Colombia had an installed capacity of 17,432.4 MW (Figure 1).[8] The country's electricity mix is characterized by a high reliance on hydropower, which in 2020 accounted for 68 per cent of total capacity. On the other hand, fossil fuel-powered plants accounted for approximately 30 per cent. Electricity generation in 2020 amounted to 69,323.5 GWh (Figure 2).[9] Approximately 73 per cent of the total originated from renewable energy sources, including almost 72 per cent from hydropower.

Electricity demand in 2020 was also lower than in 2019. The National Government and local authorities established total and partial lockdowns throughout 2020 due to the COVID-19 pandemic. This situation affected electricity consumption by industrial and commercial users, which resulted in a contraction of electricity demand — especially, between April and September 2020.[11]

Figure 1. **Installed Electricity Capacity by Source in Colombia in 2020 (MW)**

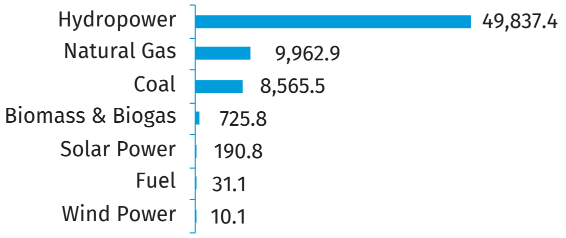


Source: XM[8]

Even though most of the electricity in 2020 was generated from hydropower, that year this source represented a smaller share of total electricity generation in comparison to 2019.[10] This was a result of declined water levels in reservoirs due to hydroclimatic conditions. Thus, between January and April 2020, the water level in reservoirs descended from 54.2

per cent to 31.8 per cent of capacity; and only by July were the reservoirs able to return to 2019 levels. The remaining electricity was generated mostly by coal and natural gas power plants.[10]

Figure 2. **Annual Electricity Generation by Source in Colombia in 2020 (GWh)**

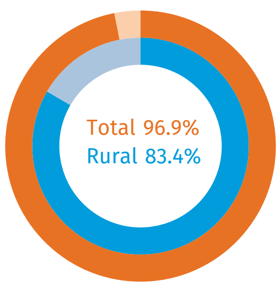


Source XM[9]

An important characteristic of the Colombian electricity sector is its integration with other countries. During 2020, Colombia exported 8.3 GWh to, and imported 42.7 GWh from, Ecuador.[12] In December 2020, the Colombian Ministry of Mines and Energy accepted the *pro tempore* presidency of the Andean Interconnection System (SINEA), a regional effort to integrate the electricity infrastructure, regulation and markets of Colombia, Ecuador, Peru, Bolivia and Chile. The country is also working on a future interconnection with Panama, which will allow the integration of the Andean and Central America markets.

In terms of electricity coverage, according to the Inter-American Development Bank's Energy Hub, the country ensured energy access to 96.9 per cent of its population in 2018 and 83.4 per cent of the rural population in 2017.[13,14] Of the population without electricity access, 97.2 per cent live in rural areas (approximately 471,000 people).[13]

Figure 3. **Electrification Rate in Colombia (%)**



Source: IADB,[13] RAP-E[14]

Note: Rural electrification data for 2017; total electrification data for 2018.

The National Government has set a goal of providing electricity to 100,000 additional households between 2018 and 2022 and, following the commitments under the Sustainable Development Goals, universal access is expected to be achieved by 2030.[15,16] This is essential for improving living conditions in the non-interconnected zones, which represent 52 per cent of the country's territory and where only 7.26 per cent of the installed capacity was renewable (21.29 MW) as of December 2020.[17,18]

The characteristics of the electricity sector of Colombia were defined in 1994 by the public utilities law (Law 142/1994) and the electricity law (Law 143/1994).[19,20] According to those laws, the electricity generation and commercialization activities are open to competition and private participation is encouraged. Therefore, during the past decades these segments have seen an increasing participation of national and foreign companies.

As a result, the main stakeholders of the electricity sector are present in both the public and private sectors. In the public sector, the Ministry of Mines and Energy sets the public policy for the electricity sector; the Energy and Mining Planning Unit (UPME) and the Energy Planning Institute for Non-Interconnected Zones (IPSE) oversee planning; the Energy and Gas Regulatory Commission (CREG) regulates the electricity market; and the Superintendency of Public Utilities enforces the said regulations. Moreover, some of the largest Colombian public and private companies belong to the energy sector, such as Enel, Empresas Públicas de Medellín, Enel Colombia, Interconexión Eléctrica (ISA) and Grupo de Energía de Bogotá. Most of these companies integrate generation, transmission, distribution or commercialization activities since the current regulations have increased flexibility in vertical integration rules.[21]

Electricity tariffs are determined by the CREG for each regional distributor, following a formula determined by CREG Resolution 91/2007. Between 2015 and 2019, average monthly prices varied between 0.07 USD/kWh and 0.12 USD/kWh, depending on the region. During 2019, the departments of Nariño and Casanare paid the highest tariffs, while Arauca and Putumayo paid the lowest tariffs.[22]

SMALL HYDROPOWER SECTOR OVERVIEW

Law 697/2001 first established a definition of small hydropower (SHP) resources (*pequeños aprovechamientos hidroenergéticos*), which limited the notion of SHP to power plants under 10 MW. Afterwards, Law 1715/2014 broadened the definition and established that SHP includes all small-scale hydropower plants of up to 20 MW.[23,24] Including power plants under 20 MW is congruent with the Colombian electric market regulation. Regardless of its source, all plants under 20 MW are considered minor plants (*plantas menores*). In Colombia, minor plants are neither subject to Central Dispatch nor used for grid balancing. Following the Colombian Hydropower Potential Atlas, adopted by the UPME, SHP can be classified into further categories of pico-, micro-, mini- and small hydropower (Table 1).[25]

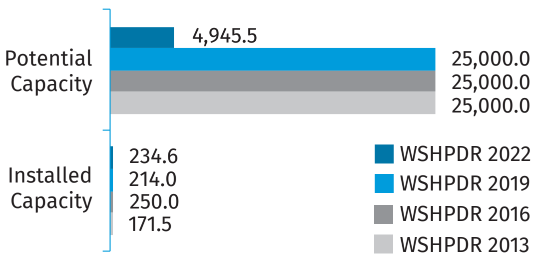
Table 1. **Classification of Small Hydropower in Colombia**

Category	*Installed capacity*
Pico	0.5 kW – 5 kW
Micro	5 kW – 50 kW
Mini	50 kW – 500 kW
Small	500 kW – 20 MW

Source: UPME[25]

As of September 2020, Colombia had 234.64 MW of installed SHP capacity for plants up to 10 MW.[26] For plants under 20 MW, the installed capacity was 900.79 MW as of December 2020.[27] In comparison to the *World Small Hydropower Development Report (WSHPDR) 2019*, the country increased by 20.64 MW its installed capacity in plants up to 10 MW.[28] The change between the data reported in the *WSHPDR 2019* and the *WSHPDR 2022* is justified by access to more accurate data (Figure 4) and new SHP capacity additions (Table 2). The potential capacity for SHP up to 10 MW is estimated at 4,946 MW, indicating a drastic change from an estimated 25,000 MW according to the *WSHPDR 2019*, which is also due to new and more accurate data.[25]

Figure 4. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Colombia (MW)**



Source: UPME,[25] WSHPDR 2019,[28] *WSHPDR 2013*,[29] *WSHPDR 2016*[30]

Note: Data for SHP up to 10 MW.

According to the Public Registry of Generation Projects (administered by UPME), as of November 2020, 43 additional hydropower projects between 1 MW and 10 MW, representing a combined capacity of 254 MW, had been submitted for approval.[31] Of these, 23 are in the Antioquia department, 8 in the Caldas department, 3 in Tolima, 3 in Risaralda, 3 in Calle del Cauca, 2 in Norte de Santander and 1 in Cauca. These projects represent 28.7 per cent of the 887 MW of new small-scale projects in the Registry that are awaiting approval and 7.3 per cent of the 3,471 MW that represents all hydropower projects in the Registry.[31]

Table 2. **List of Selected Operational Small Hydropower Plants in Colombia**

Name	*Location*	*Capacity (MW)*	*Operator*	*Launch year*
PCH La Libertad	Toca, Boyacá	1.20	EMPRESA GENERADORA Y COMERCIALIZADORA DE ENERGIA ELECTRICA DE COLOMBIA S.A. E.S.P.	2020

Source: UPME[26]

Furthermore, according to UPME's Public Registry, as of November 2020, 19 new hydropower projects between 10 MW and 20 MW, representing a total of 321 MW, had been submitted for approval. Of these, 8 are in Antioquia, 2 in Tolima, 2 in Boyacá, 2 in Cauca, 1 in Norte de Santander, 1 in Risaralda, 1 in Quindío, 1 in Arauca and 1 in Cundinamarca. These projects account for 32.5 per cent of the 988 MW of all projects of the same size in the Registry and 9.2 per cent of the 3,471 MW representing all hydropower projects in the Registry.[31]

Finally, based on a 2015 study by Pontificia Universidad Javeriana, the 2015 Hydropower Potential Atlas provides an estimate of the total run-of-river hydropower potential in Colombia by region and plant size based on turbine flow, hydraulic drop and efficiency. The country's total theoretical SHP potential is estimated at 4,946 MW (Table 3).[32] Thus, approximately 4.7 per cent of identified SHP potential has been developed so far. There is currently no available data regarding SHP sites available for development or refurbishment.

Table 3. **Theoretical Small Hydropower Potential in Colombia (kW)**

Region	*Pico*	*Micro*	*Mini*	*Small*
Amazonian Region	285	2,799	26,948	903,311
Caribbean Region	210	1,935	16,843	436,476
Andean Region*	514	5,229	47,567	1,646,204
Orinoco Region	360	3,599	35,789	1,230,958
Pacific Region	165	1,647	15,984	568,657
Total	**1,553**	**15,209**	**143,132**	**4,785,606**

Source: UPME[32]

Note: *The Andean Region is referred to in the 2015 Hydropower Potential Atlas as 'Magdalena & Cauca' due to the two main rivers that cross this region.

RENEWABLE ENERGY POLICY

The promotion of renewable energy was first outlined in Law 697/2001 and recently developed by Law 1715/2014.[23,24] According to the latter, the promotion of non-conventional renewable energy is a matter of 'public utility and social interest' due to its connection to energy security, competitiveness and environmental sustainability. This status grants non-conventional renewable energy a preferential standing in several legal topics, such as urbanism, environment, administrative and procurement matters.

The most relevant dispositions contained in Law 1715/2014 relate to fiscal incentives for non-conventional renewable projects, the promotion of small-scale projects such as self-generation and distributed generation and the replacement of diesel generation in non-interconnected zones.[24] Nonetheless, most of the legal and regulatory development of Law 1715/2014 has focused on solar and wind power projects. For instance, additional fiscal incentives have been introduced to specific components of these technologies.

In 2019, the National Government committed to increasing the non-conventional renewable energy installed capacity to 1,500 MW by 2022.[33] To meet this goal, a renewable energy portfolio standard was created by Law 1955/2019 and several renewable energy auctions have been and will be organized by the Government.[34] The expected outcome of these policies is the increase of non-conventional renewable energy installed capacity to over 2,250 MW by 2022.[34]

Furthermore, Colombia is committed to transforming its energy sector to comply with its commitment under the Paris Agreement. According to its initial Nationally Determined Contribution (NDC), the country committed to reduce by 20 per cent its greenhouse gas emissions by 2030.[35] This target could increase to 30 per cent in case international cooperation is ensured. Recently, the country updated its NDC and increased its mitigation ambition by establishing a new commitment of reducing its greenhouse gas emissions by 51 per cent by 2030.[36]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

According to Law 1715/2014, SHP is considered non-conventional renewable energy. Hence, the tax benefits created for its promotion are applicable to such projects as well, which are the main incentives for these projects currently.[24] As previously stated, the said law contains a definition of SHP, which includes all small-scale hydropower plants. This is a wider definition in comparison to what was stated in Law 697/2001, which circumscribed SHP to power plants under 10 MW.[23]

Moreover, due its classification as a non-conventional renewable energy source, SHP could be financed through mechanisms applicable to this category of technologies. The financial sector's interest in renewable energy is increasing and the appearance of future financial instruments is expected in the short term. Moreover, the Government has a fund devoted to investing in renewable energy (Non-Conventional Energies and Energy Efficiency Fund, or FENOGE) whose resources could eventually be used to finance SHP projects.

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The considerable hydropower potential of Colombia might become a liability due to the climate crisis. Due to the country's exposure to the crisis, negative effects are foreseen in different sectors and regions. Regarding water resources, it is expected that more than 50 per cent of the national territory will be affected by changes in the hydrologic systems.[33] These changes will vary depending on the region: some parts of the country will experience a reduction in precipitation, while others will see an increase. Overall, given the large share of hydropower in national electricity generation, this might eventually affect energy security of the country.[37]

For this reason, as a mitigation measure against the effects of the climate crisis, the Colombian energy policy is mainly focusing on promoting solar and wind power energy, as well as storage systems. This might dissuade investment in hydropower projects in the medium and long run.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The previous edition of the *WSHPDR*, identified several barriers to SHP development in Colombia, some of which are considered to persist over time.[28] The following points summarize the main barriers that have been identified:

- Substantial climatic variations may affect the reliability of hydropower;
- Efforts to reduce dependence on hydropower to increase energy security due to the mentioned climate variations;

- Preference of solar and wind power over SHP, even in non-interconnected zones;
- Deficit in research and development investments for SHP projects;
- Institutional fragility can discourage investment in SHP in non-interconnected zones;
- Lack of awareness or support on the part of the communities, especially in non-interconnected zones;
- Overvaluation of land in rural zones by landowners.

The key enablers for SHP development in Colombia are the favourable geographic and hydrological conditions.

Ecuador

Poullette Faraon Chaul Corona, Independent Consultant

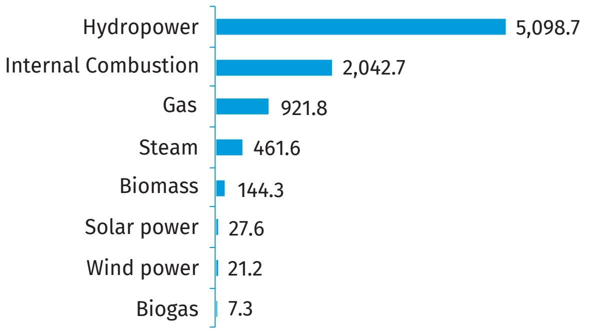
KEY FACTS

Population	17,510,643 (2020)[1]
Area	256,370 km2 [2]
Topography	Ecuador is located at the north-west part of South America, with Colombia to the north, Peru to the east and south and the Pacific Ocean to the west, where it holds an insular region, the Galapagos Islands. From north to south, the territory is crossed by the Andes Mountains (the Sierra region), which brings a diverse topography. At both sides of the Andes lie lowlands with a slightly rugged topography —the coastal region to the west and the Amazon plain to the east. The highest point of the country is Mount Chimborazo, at 6,267 metres above sea level. The country's capital, Quito, lies at an elevation of 2,850 metres.[3,4]
Climate	Given its location on the equator, Ecuador mostly has a humid tropical climate with two seasons: winter (humid) and summer (dry). The climate in the country is highly influenced by its topography, with temperature varying between 0 °C and 26 °C throughout the year. The temperatures depend on the region and elevation, with a tight inverse relationship between altitude and temperatures. The average temperature in the Galapagos Islands is 23 °C, in the coastal and Amazonian regions between 24 °C and 25 °C and in the Sierra region between 8 °C and 20 °C. The average annual temperature variation in the country is approximately 3 °C, nonetheless, the daily variations might fluctuate from 10 °C in low and coastal areas to 20 °C in the Andes Mountains.[5]
Climate Change	Studies have shown that climate change has impacted Ecuador (between 1960 and 2006) with an increase in anomalous climate events, mainly in the coastal and the Amazonian regions. There has been an increase in temperatures, their variations and rainfall, mainly in the coastal and Sierra regions. A 2021 study showed that in the last 20 years, in some areas of the coastal region, there has been an increase in rainfall, but the change in temperature has not been relevant. Regarding the Sierra and Amazonian regions, a 2021 study that analyzed the 1980-2019 period showed that, in most areas, temperature and rainfall have a decreasing tendency, however, further research is required. Hydrological systems are particularly vulnerable to changes in rainfall or droughts caused by climate change. Some areas of the coastal region are more prone to floods and droughts (Guayas and Jubones Rivers). In the Sierra region, there is more risk of landslides and erosion, and the Amazonian region might experience high risk floods (areas close to Peru). In Ecuador, a 2 °C increase in temperature is expected towards the end of the century, which could be higher in the Amazonian Region and the Galapagos islands.[6,7]
Rain Pattern	The average annual rainfall in Ecuador is 2,249 mm. High rainfall is present in the Amazonian and northern coastal regions, while it is low in the centre and southern coastal region. The coastal region presents an average annual rainfall of 400–3,000 mm, with 70–95 per cent of annual precipitation taking place between December and May. The Sierra region receives 600–3,000 mm of rainfall, with the highest precipitation in February–May and October–December. The Amazonian region receives 2,500–5,000 mm, with constant precipitation throughout the year.[8]
Hydrology	Total runoff rainwater averages 432,000 hm^3, which gives a specific annual runoff of 1,600 mm/year, exceeding the world average (of 33 mm/year). There are two main basins that absorb rainfall through a concentrated hydrographic network: the Amazon River basin, which generates approximately 70 per cent of the medium flow, and the Pacific basin, responsible for the generation of 30 per cent of the medium flow. Ecuador has 376,020 hm3 of annual water resources (361,750 hm3 surface and 56,560 hm3 underground, of which only 14,270 hm3 account for a non-repetitive volume). The average annual volume is 70,046 hm3 for the coastal region, 59,725 hm3 for the Sierra region and 246,246 hm3 for the Amazonian region. The country holds approximately 1,275 rivers and over 100 water catchment areas. Most of the rivers in Ecuador are abundant and navigable. Originated from the mountains, they drain to either the Pacific Ocean or the Amazon River.[9]

ELECTRICITY SECTOR OVERVIEW

In 2020, the total installed capacity in Ecuador was of 8,712.3 MW. By May 2021, it reached 8,725.2 MW, with renewable sources accounting for almost 61 per cent of the total capacity (hydropower, wind power, solar power, biomass and biogas) and non-renewable sources accounting for 39 per cent (internal combustion motors, gas and steam) (Figure 1).[10] The two main hydropower plants are Coca Codo Sinclair (1,500 MW), which supplies 25 per cent of the country's electricity demand, and Paute Molino (1,100 MW), which supplies 19 per cent of the demand.[11] In 2020, the installed capacity of isolated systems reached 1,372 MW, mainly in the regions of Orellana (57 per cent of the capacity) and Sucumbíos (30 per cent).[12] In addition, Ecuador holds 650 MW of installed capacity for electricity imports from Colombia (540 MW) and Peru (110 MW). Renewable energy capacity increased from 2,338.2 MW in 2011 to 5,299.1 MW in 2020, mainly due to new hydropower development. The total hydropower installed capacity went from 2,234.4 in 2011 MW to 5,098.8 MW in 2020.[13] Hence, between 2010 and 2020, renewable energy capacity more than doubled, mainly due to growth in hydropower.[14]

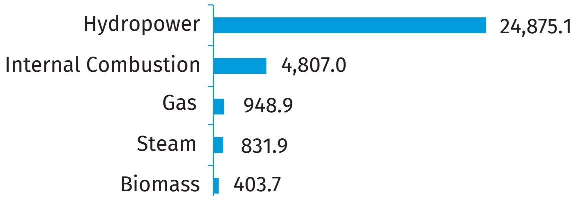
Figure 1. **Installed Electricity Capacity by Source in Ecuador in 2021 (MW)**



Source: ARCONEL[10]

National annual electricity generation reached 31,248 GWh in 2020.[12] In the period of September 2020–August 2021, electricity generation totalled 32,016 GWh (Figure 2).[10] Renewable sources (hydropower, wind power, solar power, biomass and biogas) accounted for 79 per cent of total generation, mainly through hydropower, which represented 78 per cent of the total.[10] Non-renewable sources corresponded to slightly more than 20 per cent of total electricity generation, mainly through internal combustion motors, which represented approximately 15 per cent of total generation.[10] In addition to domestic generation, during the same period, Ecuador also imported 279.7 GWh from Colombia.[10] Ecuador exported a total of 385.0 GWh to Colombia (95 per cent of total exports) and 40.8 GWh to Peru (5 per cent) during the same period.[10] In 2020, the electricity sector experienced 4,417 GWh of losses on transmission and distribution lines.[15]

Figure 2. **Annual Electricity Generation by Source in Ecuador in 2020/2021 (GWh)**



Source: ARCONEL[10]

Note: Data for the period of September 2020–August 2021.

A particularly high electricity demand was observed in Ecuador throughout 2019, having reached a historic record on 8 May (3,949.9 MW), with 91 per cent coverage from hydropower generation.[16] However, the Covid-19 pandemic had an important impact on electricity demand due to a reduction in industrial and commercial activities. By May 2020, demand started to recover again with the implementation of economic reactivation measures by the Government.[17] According to the National Electricity Operator (CENACE), the electricity demand in January–July 2021 increased by 8 per cent in comparison to 2020, due to more dynamic commercial and industrial activities.[18] Overall, between 2009 and 2019, per capita electricity consumption increased 39 per cent, reaching 1,517 kWh.[14]

In Ecuador, the power sector has regulated demand (public services) and unregulated demand (big consumers, auto-consumers and self-generators).[13] Public and private companies, duly authorized by the regulator, can generate electricity but only private ones are authorized for self-consumption. Hence, there are power plants owned by generators, self-generators (that may inject and sell surplus to the grid and distribution with generation companies (that provide public services of electricity and street lightning).[19] In December 2020, Ecuador had 139 power plants, of which 59 were private (25 hydropower, 24 solar power, 5 thermal power, 3 biomass and 2 biogas) and 80 public (40 thermal power, 39 hydropower and 1 wind power).[20] The power system is divided into two sections: the National Interconnected System (SNI), which holds most of the installed capacity, and the isolated systems, not connected to the SNI due to hard access, e.g., the Galapagos Islands and remote areas in the Amazon.[21]

The electricity sector in Ecuador is regulated by the 2008 Constitution, the 2015 Organic Law of the Public Electric Power Service (LOSPEE), its General Regulation issued in 2019, the 2019 Energy Efficiency Law, the Electricity Sector Master Plan (PME) updated every four years (the last updated version is for 2018–2027) and the National Energy Efficiency Plan (PLANEE), updated every two years. The Energy Efficiency Law regulates the National System of Energy Efficiency (SNEE) and promotes the efficient and rational use of energy as well as the service and tariffication of electric charging for vehicles. In 2017, Ecuador also issued the National Energy Efficiency Plan.[22] The electricity sector depends on the

Ministry of Energy and Non-Renewable Natural Resources (MERNNR) for the definition of policies and planning. The regulator is the Agency of Regulation and Control of Energy and Non-Renewable Natural Resources (ARC) and the electricity operator CENACE is in charge of the administration of the national interconnected grid (SNI). The Electrical Corporation of Ecuador (CELEC) is the state-owned integrated electricity company in charge of generation, transmission and import of electricity. In 2020, CELEC held most of the total installed capacity in the country at 6,366.2 MW, of which 70 per cent (4,482.2 MW) was from hydropower.[11] The National Electricity Corporation (CNEL EP) is in charge of electricity distribution and commercialization.

According to the World Bank, total electricity coverage in Ecuador in 2019 reached 100 per cent, both in urban and rural areas.[23] Nonetheless, according to ARC, in 2019, the national electrification rate was of 97 per cent, with 98 per cent expected by 2027.[24,25] Since 1999, Ecuador has a fund for rural electrification (FERUM) to increase electricity coverage in rural and remote areas.

Regulation of electricity tariffs, costs of generation, transmission, distribution and commercialization is handled by the ARC (former Agency for Regulation and Control of Electricity, ARCONEL) created in July 2020 after the merger of different regulation and control agencies. Tariffs are updated yearly observing the principles of solidarity, equity, cost coverage and energy efficiency and vary by the type of consumer (industrial, commercial and services or residential) and voltage level (low, medium, high).[26] For 2021, the total approved cost for generation, transmission and distribution of electricity was 0.09 USD/kWh. The average of differentiated tariffs applied by sector of consumers are: residential 0.10 USD/kWh, commercial 0.10 USD/kWh, industrial 0.08 USD/kWh and others 0.07 USD/kWh.[26]

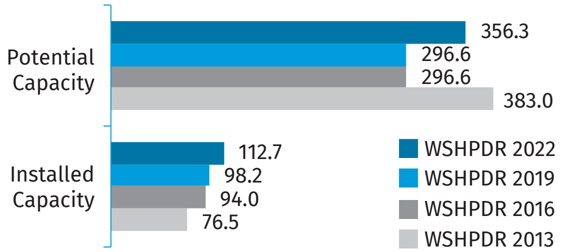
The electricity sector is subsidized, mainly for residential consumers, for example, through the "dignity tariff" and tariff incentives for the Efficient Plan for Induction Cooking and Electric Water Heating (PEC). The former is applied to 1.6 million beneficiaries and offers a reduction in tariffs for elderly people and the disabled, whereas the latter is applied to 14 per cent of households and was implemented in 2014.[11] In the last 10 years, weighted average prices of electricity have decreased from 0.04 USD/kWh in 2011 to 0.03 USD/kWh in 2020. Average prices vary depending on the type of the company: generation (0.03 USD/kWh in 2020), distribution with generation (0.04 USD/kWh in 2020) and self-generation companies (0.05 USD/kWh in 2020). Between 2011 and 2020, the highest prices were for solar power generation (0.04 USD/kWh), given that feed-in tariffs (FITs) have been in place since 2011 in order to incentivize solar power deployment.[13] In 2020, due to the Covid-19 pandemic, compensatory measures were applied, such as subsidies in favour of electricity consumers and the suspension of power cuts as well as of interests and surcharges due to the lack of payment.[27]

SMALL HYDROPOWER SECTOR OVERVIEW

In Ecuador, small hydropower (SHP) plants are considered to have up to 10 MW of capacity. Nonetheless, hydropower plants of slightly higher capacity (even up to 50 MW) are, in practice, sometimes considered as SHP. For the purpose of this chapter, the 10 MW definition will be followed.

In 2020, the installed capacity of SHP in Ecuador was 112.7 MW.[13] Total SHP potential, including developed and undeveloped potential, is estimated at 356.3 MW. The change in installed capacity since the *World Small Hydropower Development Report (WSHPDR) 2019* is due to continued growth of the sector, while the change in potential capacity is due to a new analysis, as identified in the PME (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Ecuador (MW)**



Source: ARCONEL,[11] *WSHPDR 2013*,[28] *WSHPDR 2016*,[29] *WSHPDR 2019*,30 MERNNR[31]

There are 43 SHP plants in Ecuador, including generators (19), self-generators (9) and distribution with generation companies (15), that not all inject to the grid (Table 1). SHP generation (only from generation companies) reached 267.0 GWh in 2020.[13] Two SHP plants started operations in 2020: San José de Minas (6.75 MW) and El Laurel (0.75 MW), which generated a total of 14.7 GWh in 2020.[13]

The generation expansion plan stated in the PME was updated to consider projects to be deployed between 2021 and 2024 and to be connected to the SNI. Of these projects, SHP accounts for six, with a total capacity of 42.36 MW and expected to start operations between 2021 and 2024 (Table 2).[31]

Table 2. **List of Selected Planned Small Hydropower Projects in Ecuador**

Name	*Location*	*Capacity (MW)*	*Developer*	*Planned launch year*	*Stage of development*

Source: MERNNR[31]

Ecuador has a gross theoretical hydropower potential of 91,000 MW, while technical and economically feasible potentials are estimated to be 31,000 MW and 22,000 MW, respectively.31 Hence, a considerable potential capacity remains undeveloped in the country. To use some of this hydropower potential, the PME 2018–2027 considers a total of 97 hydropower projects, for a total expected capacity of 9,429 MW. Nonetheless, SHP only accounts for 3 per cent of this total expected capacity (243.65 MW), with 47 potential projects (Table 3).[31]

Table 3. **List of Selected Small Hydropower Projects Available for Investment in Ecuador**

Bravo Grande	Esmeraldas	10	New
Alambi	Pichincha	9.5	New
San Pedro II	Pichincha	9.5	New
San Francisco II	Azuay	9.4	New
Tandapi	Pichincha	8.9	New

Source: MERNNR[31]

Note: Data as 5of 2018.

The former ARCONEL identified that the greatest hydropower potential in Ecuador (9.93 GW) is found in the Amazon basin. However, the latest tenders seek to strengthen the development of generation in the Pacific basin (with a potential of 3.5 GW), through economically competitive projects, to reduce issues with generation imbalance, especially during the rainy season in the Amazon basin. The Pacific basin has its maximum production from January to March, when the hydropower plants from the Amazon basin have low generation.[32]

RENEWABLE ENERGY POLICY

Ecuador has shown commitment to tackling climate change and protecting nature. The country signed the United Nations Framework Convention on Climate Change in 1992 (with no mandatory commitments), the Kyoto Protocol in 1999 and the Paris Agreement in 2016. It has implemented some climate change policies, such as the National Plan for Good Living 2013–2017, which defined climate change as a national issue and stated the need for a change in the energy mix; the National Climate Change Strategy 2012–2025, setting objectives for mitigation measures and increasing capacity building (mainly hydropower); and the National Climate Change Plan 2015–2018, among others.[33] The National Climate Change Strategy 2012–2025 focuses on adaptation and mitigation measures to reduce greenhouse gas emissions and defines priority sectors that are most vulnerable to climate change, which include energy, industry, agriculture and waste.[34]

Ecuador has committed to limit emissions, deforestation and air pollution, to guarantee the rights of nature and promote environmental sustainability, including the management of water heritage, and to restructure the energy mix to achieve energy sovereignty and sustainability by increasing renewable energy capacity. By 2017, Ecuador expected to achieve 90 per cent of clean energy coming from hydropower plants and aims to reduce its emissions in the energy sector by 20–25 per cent below the business-as-usual scenario.[34] Between 2010 and 2020, CO_2 emissions in the energy sector reduced by 3 per cent, mainly due to the commission of large hydropower plants, replacing thermal power generation. In September 2021, Ecuador reiterated its commitment to an average annual reduction of 6.5 million tons of CO_2 emissions equivalent until 2025, as stated in its Intended Nationally Determined Contributions.[35]

The electricity sector in Ecuador has shifted in recent years, with the National Plan for Good Living 2013–2017, towards more renewable generation, mainly hydropower.[31] The recent renewable energy policy is aiming towards pushing the development of new technologies to improve the electricity sector, such as hydrogen generation and battery storage.[36]

The PME aims to improve and expand generation, transmission and distribution in the electricity sector, with a total investment (public and private) of USD 12,679 million, of which USD 6,150 million (49 per cent of the total) correspond to the expansion of electricity generation capacity, including USD 4,675 million for hydropower plants. In 2020, there were 39 active projects, of which 21 were for renewable energy.[31] The last adjustments to the PME were made in August 2021 by the MERNNR, aiming to expand generation capacity by 1,440 MW by 2028, to be able to cover future demand, by pushing investments (approximately USD 2,200 million) in renewable energy (490 MW of solar power, 670 MW of wind power, 150 MW of hydropower and 130 MW of biomass). It is expected that 500 MW of this additional capacity will be operational by 2024.[37] Nonetheless, most of the expected added hydropower capacity corresponds to plants with over 10 MW in capacity.[31]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

There is no particular legislation in Ecuador regarding SHP, hence, the general Ecuadorian electricity sector legislation applies to SHP. According to article 3 of the LOSPEE, hydropower plants of small capacities are considered as non-conventional renewable energy sources in Ecuador. The General Regulation for the LOSPEE defines distributed generation as small power plants that are installed close to consumption and are connected to the grid. In May 2021, ARC issued a legal framework for distributed generation, for power plants with capacity between 100 kW and 10 MW, including hydropower.[38]

COST OF SMALL HYDROPOWER DEVELOPMENT

The total average cost of hydropower generation in Ecuador is expected to grow from USD 42 million in 2018 to USD 62 million by 2027.[25] The average cost estimations include administration, operation and maintenance costs; costs associated with quality, reliability and availability; costs associated with environmental responsibility; expansion of the electricity service (distribution activity); and the variable costs required for energy production. For private generation, it also includes the remuneration of the capital base of the assets in service, through the determination of an annuity with discount rates and defined useful lives of the plants.

Some preliminary average economic estimates for SHP projects between 2015 and 2019 estimate that the average investment cost varies between 3,017 EUR/kW (3,452 USD/kW) for low-head and 2,907 EUR/kW (3,326 USD/kW) for medium- and high-head (starting from 20 metres) projects. Average operation and management costs represent 3 per cent of total investment, the average lifetime of mechanical equipment is 25 years, the cost of civil works represents an average between 40 per cent (low-head) and 50 per cent (medium- and high-head) of total investment cost and the average internal rate of return is 20 per cent.[39]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

The electricity sector is considered strategic in Ecuador and it is the responsibility of the Government to plan, build and maintain electricity infrastructure, although it is also able to grant concessions to private actors to meet the country's needs. The MERNNR can grant concessions (through public tenders) for the deployment of new power capacity regarding non-conventional renewable energy, which includes SHP, following the PME. Nonetheless, hydropower plants shall be returned to the state by the end of each concession.[40] Incentives can be granted to the awarded parties. All requirements and incentives are published in each call for tenders, by block, following the PME. SHP plants can take between 20 and 40 years, depending on the plant capacity.[41]

Hydropower generation projects can be financed with public, private or mixed funds (through public-private partnerships). International organizations and agencies, such as the Interamerican Development Bank, United Nations and the French Development Agency, have also financed hydropower projects in Ecuador. Since 2000, the country has implemented FITs to support the deployment of renewable electricity capacity, which have evolved throughout the years regarding incentives and technologies. In 2014, the scheme implemented differentiated rates and became applicable to hydropower plants with capacity up to 30 MW.[39] Of the current 43 active SHP plants in Ecuador, 25 received public funding (representing 61.2 MW of the total SHP deployed capacity), 15 had private funding (48.6 MW) and 3 had mixed funding (2.8 MW).[42]

Ecuador has established a clear path towards the expansion of renewable capacity. In July 2021, the intended block of renewable projects increased from 200 MW to 500 MW, of which 150 MW are expected to be hydropower of less than 50 MW, with 30 years concessions (the First Block) and 36 months for construction.[43] In September 2021, the MERNNR announced a call for tenders to attract private investment of USD 875 million to build and operate these 500 MW of renewable energy projects, including solar power, wind power, hydropower of less than 50 MW (stated as SHP in the press release) and biomass.[44] The eight SHP projects (under 10 MW) included in this tender will account for a total of 55.35 MW (Table 4), with all of them already with definitive designs. The awarding mechanism will follow the lowest offered price. Participants to the tenders shall present warranties for USD 20,000 per MW of offered capacity and demonstrate financial and technical capacity.[31] Some incentives for private investors in new electricity generation projects include the exoneration of taxes on the outflow of foreign currency (ISD), 12-year exoneration of income tax in the national territory (8 years if the investment is in Quito or Guayaquil and 15 years if in a vulnerable region).[32]

Table 4. **List of Small Hydropower Projects Open for Tender in Ecuador as of September 2021**

Name	*Location*	*Potential capacity (MW)*
Chinambí	Carchi	9.95
Rayo 1	Cotopaxi	9.8
Chanchán	Chimborazo	9.1
San Mateo	Napo	7.3
Sardinas	Napo	6.6
Huapamala	Loja	5.2
Caluma Pasagua	Bolívar	4
Tigreurco	Bolívar	3.4

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

In Latin America, climate change has a potential to affect hydropower generation due to rising temperatures, fluctuating rainfall patterns, increased volumes of water due to melting glaciers and more constant extreme weather events. By the end of the century, these factors might cause a slight increase in the hydropower capacity factor in Ecuador, with increase in precipitation and average runoff volume.[45] In Ecuador, the coastal regions are projected to have more rainfall and the widespread flooding caused by the El Niño phenomenon is expected to increase. In the Andean region, hydropower capacity factors are projected to stay between +3 per cent and -3 per cent from the baseline.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Despite the great unexploited hydropower potential in Ecuador and the Government's policies and efforts to deploy new renewable generation capacity, there are still some challenges regarding the use of SHP. The following points summarize the main barriers that have been identified:

- Most of the planned projects to deploy hydropower capacity are focused on large-scale hydropower plants;
- Despite the identification of most hydropower potential in the Amazon basin, the development of most projects is focused in the Pacific basin to counteract generation imbalance, mainly in the rainy seasons;
- The country lacks detailed information regarding economic and technical potential of SHP, which might affect policy decisions and investment.

The following points summarize the main enablers for further SHP development:

- The recent regulation on distributed generation might boost the interest to invest in SHP projects;
- Ecuador might take advantage of the expected slight increase in hydropower capacity factor due to climate change and focus on the deployment of further SHP capacity;
- Recent tenders are showing bigger interest from the Government to seek investment in hydropower projects of up to 50 MW capacity, which might portray a bigger interest in SHP deployment in the coming years;
- The incentives considered in recent tenders for the deployment of new renewable capacity might also attract more interest to SHP projects.

French Guiana

Alberto Tena, SEDE Consulting

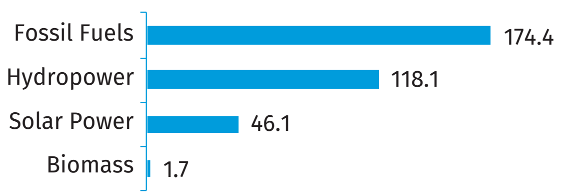
KEY FACTS

Population	281,678 (2019)[1]
Area	83,534 km2 [2]
Topography	French Guiana is situated on the north-eastern coast of South America, facing the Caribbean. The country borders Brazil to the south and east and Suriname to the west. Since 1946, it has had the status of an Overseas Department of France.3 With the exception of the coastal strip, which is made up of savannas, over 90 per cent of the country's territory is covered by rainforest. The highest peak is Bellevue de l'lnini (851 metres). Other mountains are Mont Macalou (782 metres), Pic Coudreau (711 metres) and Mont St. Marcel (635 metres). Off the coast, there are a number of small islands, including Ile de Connetable and Devil's Island located along the coast towards Brazil.[4]
Climate	French Guiana is subjected to an equatorial climate, with hot and wet weather conditions. Average temperatures vary slightly during the year, with a minimum temperature of 22 oC and a maximum temperature of up to 36 oC.[5]
Climate Change	The country is highly sensitive to climate change. Between 1955 and 2009, average temperature increased by 1.36 °C. Specifically, there is an observed increase of 1.65 °C for maximum temperatures and 1.1 °C for the average minimum temperatures.[5]
Rain Pattern	Precipitation is abundant at 3,000 mm/year, with reduced intensity in the west and the interior. There are four distinct seasons according to the pluviometry: the short rainy season lasting from the end of November to mid-February; the short summer from mid-February to the end of March; the great rainy season from April to June; and the dry season from July to mid-November.
Hydrology	There are two main rivers: the Maroni, which separates French Guiana from Suriname, and the Oyapock, located in the east and bordering Brazil for 600 kilometres. Other important rivers include the Camopi, Mana and Tompok. These are transboundary rivers and the management of their hydropower potential presupposes collaboration between the neighbouring countries.[3,6]

ELECTRICITY SECTOR OVERVIEW

Renewable energy plays an important role in electricity production in French Guiana. However, since there are difficulties with energy storage and distribution, the country still resorts to thermal power generation. The Government is focused on accelerating the energy transition and promoting sustainable energy projects, specifically, using hydropower, biomass and solar power. The total installed capacity of French Guiana in 2018 was 340.3 MW, approximately 51 per cent of which was from fossil fuels (Figure 1).[7]

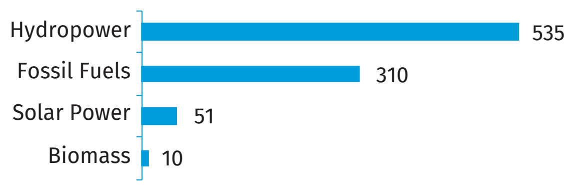
Figure 1. **Installed Electricity Capacity by Source in French Guiana in 2018 (MW)**



Source: EDF[7]

At the same time, renewable energy accounted for 66 per cent of total electricity generation in 2018, a slight reduction of 2 per cent compared to 2017.[8] This fact is linked to the conditions for hydropower electricity generation being less favourable in 2018 than the previous period. In 2018, the total production stood at 906 GWh (Figure 2), compared to 923 GWh in 2017.[7,8]

Figure 2. **Annual Electricity Generation by source in French Guiana in 2018 (GWh)**



Source: EDF[7]

French Guiana faces difficulties with supplying electricity to a large part of its territory. The littoral zone is partially interconnected by networks (except in the eastern regions), with a 414-kilometre transmission line connecting the main coastal cities of Saint-Laurent de Maroni, Kourou and Cayenne.[9] The means of electricity production for the littoral network are divided between the following power plants: the 116 MW Petit-Saut hydropower plant (EDF), which supplies on average nearly 60 per cent of the electricity consumed in French Guiana; the Dégrad des Cannes thermal power plant (EDF), which is set to be closed by 2023; the Kourou biomass power plant (Voltalia), which includes peak and back-up facilities; and other renewable energy plants, including solar photovoltaics (PV) and run-of-river hydropower.

In isolated municipalities not connected to the main grid, the means of production are limited to small electrical networks operated by EDF and supplied mainly by mini-thermal power plants and run-of-river hydropower (from the rivers Mana, Approuague, Sparouine, Maman Valentin and Inini). Almost 49 per cent of new homes built in the interior municipalities are not electrified.[10] The following municipalities are totally or partially disconnected from the electricity grid: Maripasoula, Papaïchton, Grand Santi, Saül, Saint-Georges, Camopi, Ouanary and Régina (village of Kaw).

The deficit of electric infrastructure highlights a precariousness that could be aggravated by future demographic growth.[11] Electricity demand is predicted to reach 1,280 GWh by 2030. The growing demand will have to be supplied through the construction of additional capacities, while at the same time respecting the principles established in the Multiannual Energy Programme (PPE), signed on 17 March 2017. The objective is to increase the share of renewable energy sources in electricity production to over 85 per cent by 2023.[10] However, at present, French Guiana faces important challenges in meeting this goal, since it is highly dependent on imports of fossil fuels.

Energy policies implemented by the Government are aimed at the development of modern sustainable energy infrastructure and overcoming the existing constraints, such as limited generation capacity and a lack of interconnectivity between power grids. The plans also include transmission lines to connect French Guiana to the continent's power pools and permit a large increase in interregional energy trade. The electricity transmission network of French Guiana meets the technical and economic conditions to develop such a project.

To implement energy-related policies in the territory, the local Government relies on expert entities in energy management and regulation such as the Agency for Environment and Energy Management (ADEME), Energy Regulatory Commission (CRE) and General Directorate for Territories and the Sea (DGTM). ADEME promotes and coordinates specific operations for the protection of the environment and energy management.[12] CRE is an independent authority that ensures the functioning of the electricity and gas markets in France.[13] DGTM is in charge of implementing the policies by the Ministry of the Environment, Energy and the Sea as well as those of the Ministry of Housing and Sustainable Housing.[14] The production of electricity is open to competition in French Guiana, however, according to the Law from 11 July 1975, the distribution and commercialization of electricity is monopolized by EDF.[15]

Other relevant stakeholders in the electricity sector include:
- Community of Communes of Western French Guiana (CCOG) — a public partnership entity that implements and develops rural electrification, providing specific projects for energy production (infrastructure development) as well as energy distribution (low-voltage networks);
- General Directorate of Energy and Climate (DGEC) develops and implements policies relating to energy and in particular to combating global warming and atmospheric pollution;
- French Guiana Water Office (OEG) — a public and local body in charge of water management and optimization of water as a natural resource to preserve. OEG provides studies for general interest and support for initiatives related to water treatment or energy production by hydropower systems;
- Voltalia designs and implements renewable energy projects in the country. It has carried out, among others, the hydropower project in Mana and the biomass power plant in Kourou.[16,17,18,19]

The isolation of French Guiana as an overseas territory heightens its need to produce local electricity, but at a considerable extra cost. In order to ensure that the tariffs maintain a level of equity with those of the metropole, the Government compensates the trading company EDF for these costs by means of a mechanism of tariff equalization. EDF sets different tariffs according to the power installed. For power up to 36 kV, tariffs are as follows. Tariffs for citizens range from 0.17 USD/kWh to 0.18 USD/kWh, including tax. The tariff by time slot is set at 0.20 USD/kWh, including tax, for peak hours (6 am – 10 pm) and 0.15 USD/kWh, including tax, for off-peak hours. The fixed cost for non-residential and enterprise consumers is set at 0.13 USD/kWh, excluding taxes, and the tariff by time slot is set at 0.14 USD/kWh, excluding taxes, for peak hours and 0.96 USD/kWh for off-peak hours.[20]

SMALL HYDROPOWER SECTOR OVERVIEW

The definition of small hydropower (SHP) in French Guiana is up to 10 MW. The total installed capacity of SHP is currently 5.5 MW (Table 1).[21,22] There are two SHP plants: the Saut-Maman Valentin plant in Mana and the Saut-Maripa plant in Oyapock, which has been recently refurbished. The PPE foresees the installation of run-of-river hydropower plants on the Mana River with a combined capacity of 16.5 MW between 2016 and 2023 (Table 2).[10] However, based on the planned projects, this objective will not be achieved. According to the PPE, by 2030 the total SHP installed capacity could reach 34.5 MW.[10] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, the installed capacity decreased based on more accurate data and the estimate of the potential has been added (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in French Guiana (MW)**

Table 2. **List of Planned Small Hydropower Projects in French Guiana**

Name	*Location*	*Capacity (MW)*	*Plant type*	*Developer*
Saut Belle-étoile	Mana	4.5	Run-of-river	Voltalia
Saut Sonelle	Maripasoula	3.2	Run-of-river	Voltalia

Source: ADEME,[22] DEAL[26]

Hydropower production in French Guiana is mainly concentrated at the Petit-Saut plant. Its production depends on climatic conditions and can vary considerably from one year to another. Nonetheless, the plant covers almost two thirds of the country's electricity needs. Its annual production fluctuated between 352 GWh in 2009 and 544 GWh in 2017, representing approximately 45 per cent and over 55 per cent of the electricity delivered to the main grid in those years, respectively. In 2018, the Petit-Saut plant produced approximately 510 GWh of electricity.[7]

SHP is foreseen to serve the main isolated towns on the Maroni and Oyapock Rivers. The 3.2 MW Saut Sonelle project on the Inini River, which is under appraisal, will supply Maripasoula and Papaïchton. There is also an ongoing study of a project on the Maroni River at Mankaba Soula, which is intended to supply the commune of Grand Santi.[22] The OEG carried out a study aimed at identifying SHP potential on the Maroni River, where many sites suitable for small-scale run-of-river project exist (Table 3).[27]

Table 3. **List of Potential Small Hydropower Projects in Mana Region**

Name	*Location*	*Potential capacity (MW)*	*Developer*	*Type of site (new/refurbishment)*
Grand Santi	Mankaba	1.00	Voltalia	New
Grand Santi	Abounami	1.00	Voltalia	New
Papaîcthon	Apanta pachi soula	0.50	Voltalia	New
Providence (Apatou)	Koumarou	0.15	Voltalia	New

Source: IFGR[27]

SHP production in French Guiana is marked by a drop in the dry season, requiring additional solar PV, diesel and storage. Furthermore, considering the particularities of the terrain and spatial location of hydropower generation, innovative solutions need to be provided in order to ensure the technical and economic feasibility of the projects. In this sense, the creation of adapted modular hydropower generation systems at low falls could solve the local constraints for energy generation. Ongoing projects and relevant studies are aimed at taking advantage of the small falls along the rivers, as demonstrated by the project at Trois Sauts, which is currently in a pilot phase.

RENEWABLE ENERGY POLICY

Favoured by a location close to the equator, French Guiana offers a large potential to utilize renewable energy in order to secure the needed energy supply. However, although the country has adopted an ecological transition policy, its dependence on fossil fuels remains problematic. In order to reduce the environmental footprint in French Guiana, policies must address the current constraints in terms of infrastructure and financial support.

Biomass energy is a priority in the national energy plans. However, the only operational biomass plant to date is the one in Kourou, as the plants in Saint Georges and Cacao will become functional once supply problems have been resolved. The PPE estimates an installed capacity of 40 MW from biomass by 2023 and current initiatives aim to achieve this potential. The solar PV sector has also emerged as one of the development priorities for the coming years. The targets set for 2030 by the PPE include 25 MW of solar PV with storage and 26 MW of solar PV without storage. However, the inherent difficulties in providing energy supply to inland areas are a constant and have prompted the creation of creative alternative solutions such as the development of small individual solar kits for small-scale consumption. Wind power is also in development, offering a suitable potential for exploitation in the littoral region.[28]

There is also a high interest to develop hydropower projects by the local Government, especially projects in the west of the territory, for example, in Mana. SHP projects adapted to the local needs exist, including the developed prototypes of river tidal turbines using river current. The potential of these installations could be important, especially to supply electricity to isolated inland regions. The available studies show a great potential for SHP development provided the development of innovative approaches to overcome the local constraints. Furthermore, the public bodies encourage local electricity production if connection to the transmission network is not possible, under satisfactory technical, economic and environmental conditions.

In its report published in February 2017, the CRE noted that production costs by energy technology are as follows:

- Petit-Saut hydropower plants — 120 USD/MWh;
- Saut Mama Valentin run-of-river plant —125 USD/MWh;
- Biomass power plant — 250 USD/MWh;
- Solar PV installations — 490 USD/MWh on average;
- Thermal power plants — 460–650 USD/MWh.[29]

The key laws regulating the energy sector in the country include:

- Law No. 2000-1207 of 13 December 2000 for the orientation for overseas territories (LOOM);
- Law No. 2005-781 of 13 July 2005 on the programme fixing the orientations of the energy policy (POPE);
- Law No. 2009-594 of 27 May 2009 for the economic development of overseas territories (LODEOM);
- Law No. 2015-992 of 17 August 2015 on energy transition for green growth (LTECV).[10]

COST OF SMALL HYDROPOWER DEVELOPMENT

The cost of electricity generation from hydropower in isolated regions, only accessible by pirogue, is estimated to be up to 1,530.8 USD/MWh, which is 5 times higher than the average production cost in French Guiana and 10 times higher than the selling price.

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

The Government of France has developed financial mechanisms aimed at encouraging the creation of innovative alternative solutions for renewable energy exploitation, subject to the economic viability of the projects. The public investment for the development of the hydropower sector is channelled through the French Guiana Prefecture, the French Development Agency (AFD) and the Collectivité Territoriale de Guyane (CTG), which is responsible for managing European Union funds. These entities support the developers in the preparation of their projects to ensure technical and economic feasibility and also offer financial support through such mechanisms as the allocation for infrastructure investments, provision of grants or guaranteed credits.

Additionally, other financial mechanisms for SHP include the recently launched Recovery Plan for French Guiana, a financial injection that includes the reinforcement of support for the development of renewable energy technologies.[30] The legislation of France also foresees the creation of an exceptional fund for investment in overseas territories to support the funding of projects of collective public facilities.[10]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

French Guiana is very sensitive to the climate crisis since the distribution and proportion of dry and wet seasons modify drastically the available water resources. These fluctuations are unpredictable and introduce a significant risk of supply disruption in the driest years. In order to overcome these difficulties, French Guiana opted for building thermal power plants to secure the supply, in contradiction to the plan to use 100 per cent renewable electricity production.

Hydropower plants require intelligent solutions to manage the water supply. For instance, the Petit Saut hydropower plant has an optimization system to set the water use value, which chooses the most appropriate time for using the water stored in the reservoir. In this way, its management is optimized to limit the needs for additional power requirements and to reduce the use of thermal power. This optimization system takes into account the great interannual variability of hydraulic inputs, knowing that between dry and wet years the production of the Petit Saut plant can vary by a factor of two (from 280 GWh in a dry year to 540 GWh in a wet year).[7]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The barriers to SHP development in French Guiana are as follows:

- French Guiana is highly sensitive to climate change, due to the variability of rainfall between the rainy and dry seasons;
- The development of other renewable energy sources, such as solar PV or biomass, is a priority, although numerous plans and studies to develop the SHP sector exist, especially in the east of the country;
- The remoteness of the transmission or distribution network and the environmental impacts of the projects are critical obstacles, especially in isolated areas where difficulties associated with transporting materials should be considered;
- The cost of energy production in French Guiana is considerably higher than in metropolitan France;
- There are administrative delays to obtain permissions to build electrical installations.

The enablers for further SHP development are:

- The planned closure of the Dégrad-des-Cannes thermal power plant favours the use of renewable energy sources, including SHP, to meet the country's energy demand;
- Great potential for SHP development given the variety

of suitable sites across the territory;
- Local policies favourable to the exploitation of SHP for the energy transition.

Guyana

Tobias Dertmann, Hydropower Consultant; and International Centre for Small Hydro Power (ICSHP)

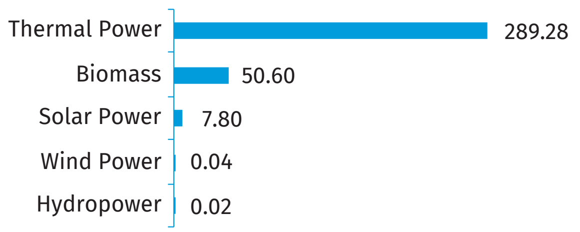
KEY FACTS

Population	743,699 (2019)[1]
Area	214,999 km2 [2]
Topography	The terrain of Guyana is mainly characterized by tropical rainforest with flat areas at the coastline and some mountainous areas in the so-called Hinterland. The Pakaraima Mountains in the west rise to 2,772 metres at Mount Roraima, which is the highest point of the country.[2,3]
Climate	The climate is tropical, characterized by high temperatures and humidity. Temperatures average 25 °C with little variation throughout the year.[3]
Climate Change	The main impacts of climate change in Guyana include: increases of heavy rainfall, possibly leading to flooding; longer periods of draught; sea level rise and storm surges, especially in coastal zones; and increases in temperature and decrease of annual precipitation. It is expected that temperatures will increase by 1-4 °C in the country by the end of the century, while sea levels will rise by 0.3-0.9 metres.[4]
Rain Pattern	Precipitation is generally high, ranging from 1,500 mm to over 4,000 mm, with a pronounced rainy season from May to July and a shorter one from December to January.[3]
Hydrology	Guyana is called the Land of Many Waters owing to the abundance of streams, rivers and creeks. The largest waterways are the Corentyne, Berbice, Essequibo and Demerara Rivers. Particularly in the relatively unpopulated southern part of the country, there are many falls along the rivers while the rivers' gradients decrease towards the more densely populated areas at the coastline.[3]

ELECTRICITY SECTOR OVERVIEW

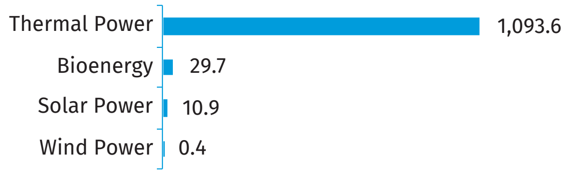
The electricity system of Guyana consists of an integrated network at the coast, which supplies electricity to approximately 90 per cent of the population, various clustered island systems in Region 3 (Essequibo Islands–West Demerara), six Hinterland island grids and self-generators, which supply individual smaller communities and mines. Installed capacity in Guyana reached a total of 347.7 MW in 2018 and renewable sources made up almost 17 per cent of the total (Figure 1).[5] Total electricity generation in 2019 stood at 1,134 GWh, with thermal power having surpassed any other source, at 1,094 GWh (Figure 2).

Figure 1. **Installed Electricity Capacity by Source in Guyana in 2018 (MW)**



Source: ETI[5]

Figure 2. **Annual Electricity Generation by Source in Guyana in 2019 (GWh)**

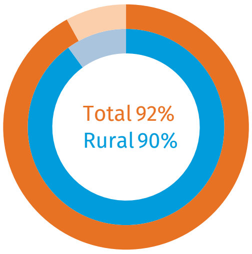


Source: GEA,[6] Guyana Chronicle[7]

While the electrification rate at the coast is high, most of the Hinterland communities do not have a regular electricity supply. In 2019 the nationwide electrification rate stood at 92 per cent, including 97 per cent in urban areas and 92 per cent in rural areas (Figure 3).[8]

The country's primary electricity utility is Guyana Power and Light Inc. (GPL), a wholly state-owned, vertically integrated utility company whose licence will expire in 2024. In many smaller Hinterland communities such as Lethem, Mahdia and others, state-owned electricity companies supply electricity to public institutions and households. In some cases, it is provided on a 24-hour basis and in others for several hours per day only. In the Hinterland electricity systems, various private electricity providers are established, foremost in conjunction with mining operations that supply the nearby communities with electricity.

Figure 3. **Electrification Rate in Guyana in 2019 (%)**



Source: World Bank[8]

Electricity is mainly produced with diesel and heavy fuel oil (HFO) generators, with the exception of a small share of co-generation from bagasse and both on-grid and off-grid solar power systems and limited contributions from hydropower and wind. In 2020, GPL demand from its customers in the coastal area was forecasted at 926 GWh.[9]

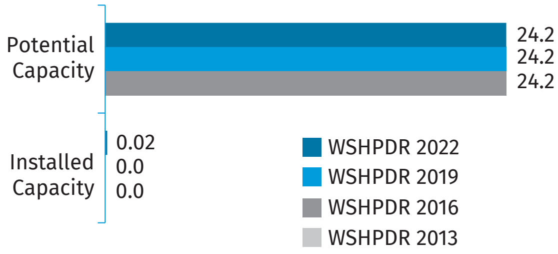
The Public Utilities Commission (PUC) regulates the electricity sector. The National Energy Policy and the Electricity Sector Reform Act (with 2010 amendments) provide the platform for the participation of independent power producers (IPPs). The Guyana Energy Agency (GEA) is mandated to advise the Minister with the responsibility for electricity and energy on matters related to energy, execute studies, formulate energy policies and regulate the import of petroleum products. However, GEA has no general role as an electricity or energy sector regulator. Besides GEA, there is the Hinterland Electrification Company Inc. (HECI), which is attached to the Office of the Prime Minister and is responsible for the electrification of the Hinterland communities. The office of the Minister with responsibility for energy, currently the Prime Minister, issues licences for IPPs or electric utilities.

GPL's electricity tariff rates for residential, commercial and industrial consumers are USD 0.22, USD 0.32 and USD 0.29 per kWh on average, respectively. Rates in the Hinterland systems are higher with the generation cost reaching as high as USD 0.50/kWh. Current electricity tariffs are by far not cost-reflective and the Government subsidizes Hinterland and GPL's operations when fuel prices are high.[9] The Government of Guyana is currently working on the 165 MW Amaila Falls hydropower project, which will significantly aid in the reduction of the overall cost of generation, and by extension, reduce electricity tariffs. The project will also improve the technical stability of the power grid with an energy mix that will include intermittent renewable energy sources.[9]

SMALL HYDROPOWER SECTOR OVERVIEW

The definition of small hydropower (SHP) used by Guyana applies to capacities up to 5 MW. The potential capacity for SHP is estimated to be 24.2 MW for the 5 MW threshold and 92 MW for the 10 MW threshold. Installed capacity was 0.02 MW as of 2021. Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, the potential capacity remained unchanged, and the installed capacity has increased due to a newly commissioned plant (Figure 4).

Figure 4. **Small Hydropower Capacities in the WSHPDR 2016/2019/2022 in Guyana (MW)**



Source: Guyana Chronicle,[7] *WSHPDR 2016*,[10] *WSHPDR 2019*[11]

Note: Data for SHP up to 5 MW.

In 2019, a new SHP plant (Hosororo) was assessed and built (Table 1). This comes several years after the shutdown of the 500 kW Moco-Moco hydropower plant in 2003, following damages caused by a landslide. The Hosororo project was technically and financially supported by the German Development Agency (GIZ) and developed by GEA. It has an installed capacity of 20 kW and is connected to the small local distribution network, feeding into the electrical grid of the Mabaruma Power Company. The gross head is approximately 32 metres. The inlet structure is connected to the turbine house via a 300-metre-long pipeline. As the first hydropower plant to be restarted after more than 20 years, the project also serves as a signal to the whole hydropower sector in the country to increase the ambition within the responsible institutions.[6]

The planning, construction and commissioning for the Hosororo plant was carried out by the GEA. The project is considered as a capacity building project to increase the training of local hydropower engineers and a potential training and testing hub for the entire Caribbean (CARICOM) region. With the construction of the plant, other hydropower projects in the country have been accelerated in development (Table 2). Nevertheless, continuous operation and grid feeding into the local supply network has already taken place in the test phase and is to be operated on an ongoing basis.

Name	*Location*	*Capacity (MW)*	*Head (m)*	*Plant type*	*Operator*	*Launch year*
Hosororo	Mabaruma	0.17	32	Run-of-river	Mabaruma Power Company	2019

Source: Guyana Chronicle[7]

The Islamic development bank (IsDB) is financing the rehabilitation of the Moco-Moco hydropower plant (700 kW) and a new construction of the Kumu (1.5 MW) plant. The tender for the double project was planned to be launched in 2021. The project will be integrated into the Lethem Power Company's electrical system. The fast-growing border town in the south-west of the country aims to generate 100 per cent of its electricity from renewable sources in the near future. The two hydropower projects will play a key role in achieving this goal.[12]

The 0.5 MW (2 x 0.25 MW) Moco-Moco hydropower project, located in Region 9, was first commissioned on 22 November 1999. The hydropower plant was designed and built by the Institute of Water Conservancy and Hydropower (Shijiazhuang, China) through a joint arrangement between the Governments of Guyana and China. The Moco-Moco plant is a run-of-river, diversion-type with a high-water head. It supplied power to the community of Lethem and its environs. However, severe rainstorms and the subsequent landslide in 2003 resulted in a fractured penstock. The Government has since been actively discussing options for its restoration. A geotechnical survey to inform the project design and assist in de-risking the project was expected to be completed in 2021.

The current concept of the project is to rehabilitate the defunct hydropower plant and increase the installed capacity to 0.7 MW. The site is located on the Moco-Moco Creek, which is a part of the Amazon River system originating from the north of the Kanuku Ranges and converging into the Takutu River. The project will provide electricity to Lethem and its environs and will form a complementary suite of planned energy initiatives in the town, consisting of the hydropower plant and a solar photovoltaic (PV) installation.

The proposed Kumu hydropower project entails the installation of a 1.5 MW plant and construction of a transmission line.[13] The Kumu Creek, located in Region 9 (Upper Takutu–Upper Essequibo), is also part of the Amazon River system. The Kumu site is situated 9.5 kilometres away from the Moco-Moco plant and 13 kilometres south-east of the town of Lethem. The project will operate as a run-of- river plant with an ultra-high head potential of more than 500 metres. Its topographical specifications can accommodate the construction of a small reservoir on the top of the mountain plateau to maintain a constant water level for operation of the plant. The combined operation of the Kumu and Moco-Moco hydropower plants, together with the planned solar PV installation, could result in 100 per cent renewable electricity generation in Lethem.

Studies have estimated the potential capacity at selected sites, such as Eclipse Falls (3–5 MW) and Tumatumari (1.5 MW). Tumatumari, utilizing water from the Tumatumari Falls on the Potaro River, Region 8, was constructed in 1957 by British Guiana Goldfields Limited and operated until 1959 when mining operations ceased. In 1969, the Government of Guyana recommissioned the plant to serve the Guyana National Service Camps at Tumatumari and Konawaruk. The development included an embankment dam, a concrete overflow dam and a two-unit powerhouse with an installed capacity of 1,500 kW using two 750 kW Francis turbines.[16]

Table 2. **List of Planned Small Hydropower Projects in Guyana**

Name	*Location*	*Capacity (MW)*	*Head (m)*	*Plant type*	*Developer*	*Planned launch year*	*Stage of development*
Kumu	Kumu River, Region 9	1.50	550	Run-of-river	GEA	2024	Tender

In continuing efforts to collect data on potential hydropower sites for future development, hydrological data collection continued at Paruima, Region 7. A technical assessment was conducted at Chenapau, Region 8, to explore the possibility of developing a pico-hydropower plant.[16] Some SHP projects available for investment are listed in Table 3.

RENEWABLE ENERGY POLICY

In order to preserve the country's rich fauna and flora, each new project must be scrutinized for ecological compatibility. Environmentally-friendly projects, however, are welcomed and have good chances of being approved. The Environmental Protection Agency provides basic requirements for acquiring environmental authorization for hydropower project developments. However, this is the country's first experience of setting rules for environmental evaluation and further elaboration thereof will be required. Currently, the Government prepares to attract developers of SHP projects by means of public tendering processes for selected projects.

The procurement process follows the following steps: approval of tender documents, advertisement and purchase of tender, submission of bidding documents, evaluation, approval of the evaluation report, contract award, execution, monitoring and evaluation, defects liability period and project closure. The Public-Private Partnership (PPP) Policy Framework was developed in 2018 for infrastructure projects including hydropower plants and other renewable energy projects. The details of the PPP process have not been put into practice yet for hydropower plants and energy farms.

The National Energy Policy of Guyana of 1994 contains an outlook from 1994 to 2004.[17] In 1994, the policy already prescribed energy conservation and a preference for domestic energy sources over imported fuels. The 1994 policy was outdated and required updating considering the latest technological and other developments. The Low Carbon Development Strategy (2013) aims to introduce climate smart infrastructure and the use of clean energy, installation of energy efficiency and conservation technologies as well as rural electrification programmes.[18] The National Energy Policy was updated in the form of a Green Paper in 2017.[19] Presently, the Government of Guyana aims to provide affordable, stable and reliable energy to benefit both households and businesses and will pursue a programme with an energy mix that includes hydropower, natural gas, solar and wind power. This programme will lead to more than 400 MW of newly installed capacity for residential and commercial users over the next five years and a reduction in the cost of energy by at least 50 per cent. There are currently no feed-in tariffs for electricity generated from renewable energy sources but this remains a priority.

The Electricity Sector Reform Act (ESRA) of 1999 mentions the use of renewable and alternative energy but does not explicitly promote the use thereof by creating preferences or other incentives.[5,15] Nonetheless, a study was conducted on the legal and regulatory framework of the electricity sector with a view to facilitate private sector investment in renewable energy development through IPPs and distributed generation. The study has proposed amendments to the ESRA and other relevant laws.

In the past, there was no structured approach to developing the country's hydropower resources. Instead of taking a proactive role in developing the resources by tendering concessions or generation capacity portfolios, the Government responded to proposals brought forward on the initiative of individual developers. The current approach to public tendering of projects outlines rules for participants in the bidding process. In 2016, the Cabinet issued instructions to invite proposals from interested groups for renewable energy projects supply in the Bartica community, Lethem (Moco-Moco) and other identified communities.[20] However, alternative funding sources were subsequently secured and the projects in these communities are now being developed through engineering, procurement and construction (EPC) contracts.

Due to the inexperience and lack of precedence in the development and operationalization of hydropower plants in Guyana, potential developers see themselves confronted with obscure processes for obtaining the various licences and meeting the rules for the application and project development process. This applies to planning licences, operating licences, environmental permits and any other applicable permits. This results in uncertainty for developers regarding the application duration, application cost and likely outcomes. Developers typically put forward high expectations regarding revenue and payback time, which the projects are rarely able to satisfy. On the other hand, the Government did not grant sovereign guarantees for such projects in the past, which, if done, would make it easier and cheaper for developers to mobilize financing. Here, both parties need to seriously consider the advantages and disadvantages of initiatives to de-risk such hydropower projects. The Government of Guyana has also introduced an online platform for investors.

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

The National Energy Policy of 1994 speaks of SHP in the capacity range between 500 kW and 5,000 kW. Currently, hydropower initiatives are considered and supported by the Government.[21] The Guyana Power Sector Policy and Implementation Strategy was passed by the Cabinet in 2010 outlining the way forward for hydropower development.[22] Additionally, the Low Carbon Development Strategy (2013) included the Amaila Falls hydropower project as a major part of the country's renewable energy transition.

Country-specific estimates on the cost of SHP are not yet available due to the statistically insignificant number of operational projects in the country.

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

Value-added tax and import duty exemptions are applied to machinery and equipment for obtaining, generating and utilizing energy from renewable energy sources, including solar panels, solar lamps, deep-cycle batteries, solar generators, solar water heaters, solar cookers, direct current (DC) solar refrigerators, DC solar freezers, DC solar air conditioners, wind turbines, water turbines and power inverters. There is also a one-off tax holiday of two years for corporation tax applicable to importers of items for wind and solar energy investments. Moreover, investments (with the exception of wind and solar power) may also benefit from exemptions from property, corporate, withholding and capital gain taxes at the discretion of the Minister of Finance for periods of five or more years depending on the type of new employment created.[23]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

Due to the general extremely high annual tropical precipitation amounts, there is no significant impact of the climate crisis on the operation and planning of hydropower plants. Different climate models offer different estimates of the changes in precipitation amounts. Locally, both increases and decreases in total precipitation amounts are expected. The projected change in precipitation amounts is on average approximately 100 mm/year.[4] This corresponds to a change of approximately 4 per cent per year. The possible impact on the hydropower systems can therefore be classified as low in Guyana.

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Guyana has an outstanding and yet unexplored hydropower potential, including a great number of SHP sites throughout the country that remain completely undiscovered. The Hosororo SHP plant built in 2019 was the first milestone for the further development of hydropower in the country. Since then, more projects have been launched and many more are to follow. After decades of stagnation, many new competencies in hydropower have been achieved in recent years. However, there are more hurdles ahead to further incentivize developers and investors. The country's vast hydropower potential needs strong de-risking efforts aimed at improving the attractiveness of hydropower projects, possibly bundling several projects together to channel development to a successful outcome.

The following points summarize the main barriers that have been identified:

- The great distances between hydropower sites and load centres and the difficult access into the Hinterland;
- In most cases, the construction of expensive access roads has to be included into the project budget jeopardizing the viability of projects;
- Long transmission lines between project sites and load centres put a significant financial burden on the projects, particularly considering the ratio between line length and the power demand;
- Lack of technical expertise in undertaking hydropower projects among local agencies and contractors.
- Hinterland villages face the problem of clustered settlements with large distances among villages and even individual houses resulting in high cost for connection of households to the electricity supply;
- Quantity and quality of hydrological and meteorological data to support hydropower development;
- Access and understanding of suitable software and satellite data for the generation of hydrological models to support hydropower development;
- Poorly gauged or ungauged rivers for the collection of physical data (flow, water level, rainfall, etc.)[8]

The following points summarize the main enablers that have been identified:

- Guyana has nearly four times its per capita economic output since 1990, triggering the development of internal hydropower capacities after years of stagnation in the past;
- the commitment of individual decision-makers in the country has meant that, despite major hurdles, the first (after 20 years) small hydropower station was able to start operating in 2019;
- Increased investment flows in SHP projects from the GEA in recent years.

Paraguay

Laura Stamm, International Center on Small Hydro Power (ICSHP)

KEY FACTS

Population	7,132,530 (2020)[1]
Area	406,752 km2 [2]
Topography	Approximately two thirds of the country is covered by the Gran Chaco, a flat tropical region extending north-west into Bolivia and Argentina. Separated by the central Paraguay River, the Paraná Plateau in the eastern region is an extension of the Brazilian Plateau and varies in elevation from 50 metres to 760 metres. The Amambaí Mountains run along the border with Brazil, then turn and run eastwards as the Mbaracayú Mountains. The country's highest peak, Mount San Rafael at 850 metres, is located in the Cordillera de San Rafael in the south-east.[2]
Climate	The climate is tropical in the north-western Chaco region and subtropical in the south-eastern Paraneña region. The winter season lasts from May to August, with July being the coldest month. Temperatures typically remain between 16 °C and 24 °C, but near freezing temperatures accompanied with frost will occasionally occur. The summer season lasts from October to March, with January being the warmest month. Daytime temperatures reaching 38 °C are common. Summer is also the wetter season with increased humidity and rainfalls.[2]
Climate Change	Climate change is expected to largely affect the precipitation pattern in the country. While the drier El Chaco region in the west will most likely experience an increase in droughts, the wetter Paraneña region in the east expects an increase in floods. Average temperatures are expected to increase by between 2.6 °C and 4.8 °C by the end of the century, depending on human acitivity.[3]
Rain Pattern	There are regional and seasonal variations in rainfall. The eastern region receives the most rainfall with an average of 1,650 mm per year. The western region is considerably drier, receiving an average of 760 mm per year. Throughout the country, rainfall is heaviest between October and April.[2]
Hydrology	The Paraguay and Paraná Rivers are the two main watercourses in the country. They define most of the borders and their basins provide all of the drainage. The Paraguay River runs from north to south, splitting the country into its two major regions. The major tributaries entering the Paraguay River from the east are the Apa, Aquidabán, Ypané, Jejuí Guazú and Tebicuary Rivers. The Paraná River outlines the country's eastern and southern borders. The major tributaries are the Acaray and Piratiy Rivers. The country has two major lakes, Lake Ypoá and Lake Ypacaraí; both are situated towards the south.[2]

ELECTRICITY SECTOR OVERVIEW

Paraguay is a country with abundant energy resources, particularly hydropower, and has one of the world's highest electricity generation rates per capita (approximately 6,500 kWh).[4] In 2020, total electricity generation in the country was 46,373 GWh; 46,371.1 GWh of which was from hydropower and the remaining 1.9 GWh from thermal power (Figure 1). Of the total generated, 28,004 GWh, or 60 per cent, was exported, primarily to Brazil and Argentina. The total electricity consumed in Paraguay in 2020 was 13,719 GWh, of which 47 per cent was used by the residential sector, 49 per cent was used by the industrial and commercial sectors and 4 per cent was used for public street lighting. Losses accounted for the remaining over 4,000 GWh of electricity.[5]

Figure 1. **Annual Electricity Generation by Source in Paraguay in 2020 (GWh)**

Source: VMME[5]

The total installed capacity of Paraguay is approximately 8,816 MW (Figure 2). Most of the capacity comes from two binationally operated hydropower plants (HPPs). The Itaipú HPP, jointly operated with Brazil, provides 7,000 MW to Paraguay and a further 1,600 MW are from the Yacyretá HPP, jointly owned with Argentina. There is also the 210 MW Acaray HPP, which is solely Paraguayan owned.[4] Ongoing projects to connect all remote areas to the hydropower network have resulted in the recent closing of almost all thermal power generation, with the exception of 6.1 MW remaining in El Chaco region.[6] In 2019, the country reached a 100 per cent electrification rate, including all rural areas.[7]

Figure 2. **Installed Electricity Capacity by Source in Paraguay in 2020 (MW)**

Source: VMME[4]

While the electricity sector in Paraguay is virtually 100 per cent sourced from hydropower, the total energy production mix including energy used for transportation or industrial processes also features a significant amount of biomass. In 2020, 53 per cent of total energy produced was from hydropower and 47 per cent from biomass. Any petroleum-derived energy used in the transportation and industry sectors was all imported.[8]

The Vice Ministry of Mines and Energy (VMME), created in 1990, is the governmental body that oversees the energy sector as a whole. The National Administration of Electricity (ANDE) is a state-owned utility that controls the electricity subsector, including generation, transmission and distribution. ANDE is responsible for operating the share of Paraguay in the binational HPPs and fully runs the Acaray HPP. ANDE operates the bulk of the transmission and distribution network, but there are also some small, private distributors connected to the national grid, such as CLYFSA and COOPERATIVA MENONITA.[4,8]

The tariffs for the electricity sector are determined by ANDE, as per Law 2199/03, and vary depending on the type and volume of consumption (Table 1).[9] The Social Rate of Electricity Law 3480/2008 stipulates that people of a lower income level who fulfil certain requirements can pay the discounted, social tariff. This provides a 75 per cent discount for users of under 100 kWh per month, 50 per cent discount for users of between 101 kWh and 200 kWh and a 25 per cent discount for users of between 201 kWh and 300 kWh.[10]

Table 1. **Electricity tariffs in Paraguay**

Type	*Average tariff (USD/kWh)*
Residential	0.059
Industrial	0.043
Government	0.052
Street lights	0.055
Other	0.052
Export	0.120

Source: ANDE[9]

The electricity system of Paraguay is prone to high system losses, frequent blackouts and shortages during inclement weather, which can negatively affect commercial activities in the country. The two HPPs that supply most of the power for the whole country are both located on the eastern and southern national borders and are therefore far from the central, western and northern regions. Due to limited capacity on the insufficiently developed transmission and distribution network, efficient transfer of the energy is a challenge, resulting in the losses and shortages.[11]

At the same time, the demand for electricity is expected to grow both in Paraguay and the neighbour countries it exports hydropower to. In order to increase the efficiency of the current network and satisfy the demand increase, a 2021–2030 Works Master Plan was created. In this plan, several projects that will modernize the transmission system were outlined. Included is the construction of new transmission lines, some more than 200 kilometres in length. The total cost is expected to be more than USD 126 million.[12]

SMALL HYDROPOWER SECTOR OVERVIEW

The definition of small hydropower (SHP) in Paraguay is up to 50 MW. As of 2021, there were no SHP plants in operation. While total SHP potential is unknown, based on the projects planned to be completed by 2036, it is possible to conclude that there is at least 116.3 MW of undeveloped potential.[13] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, both installed and potential SHP capacity remained unchanged since none of the planned projects have been completed during these years (Figure 3).

Figure 3. **Small Hydropower Capacities in the WSHPDR 2016/2019/2022 in Paraguay (MW)**

Sources: ANDE,[13] *WSHPDR 2019*,[14] *WSHPDR 2016*[15]

Paraguay has an outstanding hydropower potential estimated at 130 TWh annually, while technical and economically feasible potential is estimated at 101 TWh annually, which greatly exceeds the country's current installed capacity.[14] Under the 2021–2040 Generation Master Plan released by ANDE in February of 2021, the construction of several SHP plants is foreseen in order to increase the energy stability as well as offer economic opportunities in remote areas. With the completion of these smaller, more spatially spread-out plants it is hoped that losses and shortages will significantly decrease along with the reliance on the three existing hydropower plants. There are plans to install 18 SHP plants between 2029 and 2036 with a combined capacity of 116.3 MW (Table 2).[13] All of these 18 plants will feature two turbines, with each turbine having half of the total capacity listed for the plant.

Table 2. **List of Planned Small Hydropower Projects in Paraguay**

Name	*Capacity (MW)*	*Planned year of completion*
Ypané 1	3.2	2029
Ypané 2	4.2	2029
Ypané 3	4.2	2029
Ypané 4	4.3	2029
Ypané 5	5.0	2029
Ñacunday 1	8.0	2031

RENEWABLE ENERGY POLICY

The National Climate Change Mitigation Plan of 2017 and the Generation Master Plan 2021–2040 both stress the importance of expanding and diversifying renewable energy. While the country produces a negligible amount of non-renewable energy, only two sources of renewable energy are developed: large hydropower and biomass. It is anticipated that diversifying into SHP and solar power will help energy stability and economic development in the country. Investments in solar photovoltaics in the western Chaco region have already begun, as well as the designation of sites for the planned SHP projects. Although the Government of Paraguay was originally interested in expanding into wind energy, various international scientific organizations found that given the topography, there is no significant potential in wind power.[13,16]

To encourage the diversification of renewable energy, the Senate passed a bill in November 2021 on Regulating the Promotion, Generation, Production, Development and Use of Electrical Energy from Non-conventional Non-hydraulic Renewable Energy Sources. The bill suggests the promotion of investment in renewable energy besides large hydropower, especially from foreign entities. It also provides the institutional framework for licensing projects above 1 MW, which the VMME would have the authority over. Additionally, it suggests financial incentives to be put in place, such as exemption from the value-added tax amongst others.[17]

ANDE was the monopoly controller of the electricity market until 2006, when Law 3009/2006 was adopted. The law opened the market to independent power producers (IPPs) to generate and transport electricity for domestic consumption or export. The law applies to all renewable energy resources with the exception of hydropower plants larger than 2 MW, in which case ANDE maintains its preferential rights.[17]

SMALL HYDROPOWER LEGISLATION AND REGULATIONS

Hydropower development projects are subject to Law 294/1993, which states that any new infrastructure development, including any hydraulic works projects, must have an environmental impact assessment approved by the Secretary of the Environment before construction.[18] Specifically regarding the water supply of a project, Law 3239/2007 on Water Resources of Paraguay requires an inventory of water resources to be carried out, as well as an approved permit for its use.[13]

COSTS OF SMALL HYDROPOWER DEVELOPMENT

With no previously existing SHP plants in Paraguay, the costs associated with developing a new project can only be estimated. The Master Generation Plan predicts an investment of approximately USD 2,500 per kW for SHP projects. The plan is to invest a total of USD 505 million to complete all 18 planned projects by 2036. The cost for the projects individually is unavailable.[13]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Paraguay has a great potential for both large and small hydropower. However, the development of SHP is particularly hindered by the institutional structure and the market conditions of the country's electricity sector, namely:

- Lack of incentives for ANDE to alter the current model of operation of the electricity system and the generation of electricity;
- Insufficient demand to incentivize IPPs to enter the market;
- New policies are focused on promoting non-hydraulic sources of renewable energy.[14,16]

Some enablers to SHP development in Paraguay include:

- The untapped potential of hydropower in the country, including on smaller rivers, is significant;
- With energy stability and transmission losses being a major concern, SHP located closer to consumers could help alleviate this problem.[13]

Peru

Julio Montenegro-Gambini and Frank Charlez Ramírez Bogovich, Wasser World Ltd.

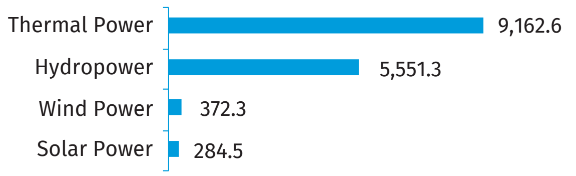
KEY FACTS

Population	32,971,846 (est. 2020)[1]
Area	1,285,215.6 km2 [2]
Topography	Peru is divided into three topographical regions: the Pacific coast, the Andean highlands (known as La Sierra) and the Amazon rainforest. Elevation ranges from 0 metres along the coast to 6,768 metres in the highlands.[3]
Climate	Peru has 28 of the world's 32 climates, a diversity created by the presence of the Andes Mountains, the cold Humboldt Current and El Niño. Temperatures vary from below 0 °C to 40 °C. Average annual temperatures are 18–20 °C on the coast, 8–11 °C in the highlands and 24 °C in the Amazon region.[3]
Climate Change	By the second half of the 21st century, climate change scenarios show an average nationwide increase in minimum temperatures of between 2 °C and 3 °C and an increase in maximum temperatures of between 4 °C and 6 °C, relative to the period 1971–2000. Precipitation is projected to increase by 10–20 per cent.[4]
Rain Pattern	Annual precipitation in Peru ranges from less than 20 mm to more than 8,000 mm. The Pacific coast is an arid region. However, during El Niño episodes the northern coast can face major flooding with precipitations higher than 4,000 mm. On the central and southern coasts, rainfall is scarce with a total range between 10 mm and 150 mm.[3]
Hydrology	The rivers of Peru are divided into three large basins: the Atlantic basin that covers almost 75 per cent of the territory of Peru and contains almost 98 per cent of the country's water resources; the Pacific basin, covering almost 22 per cent of the territory and containing approximately 2 per cent of the water resources; and the closed Lake Titicaca basin, covering less than 4 per cent of the territory and containing less than 1 per cent of the water resources. The main rivers of Peru are the Amazon, Madre de Dios, Putumayo, Napo, Maranon, Huallaga, Santa and Apurimac.[2,3]

ELECTRICITY SECTOR OVERVIEW

Total installed electricity capacity in Peru was 15,370.7 MW in 2020. Of this total, 9,162.6 MW (approximately 60 per cent) was provided by thermal power (including both renewable and non-renewable sources), 5,551.3 MW (36 per cent) by hydropower, 372.3 MW (2 per cent) by wind power and 284.4 MW (2 per cent) by solar power (Figure 1). Total available capacity the same year was 14,562.7 MW.[5]

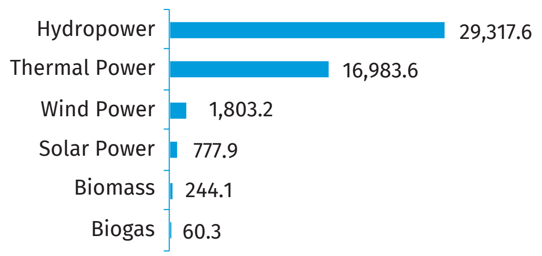
Figure 1. **Installed Electricity Capacity by Source in Peru in 2020 (MW)**



Source: OSINERGMIN[5]

Total net electricity generation in 2020 amounted to 49,186.7 GWh, representing a 7 per cent decline from 52,899.1 GWh produced in 2019. In 2020, hydropower produced 29,317.6 GWh (approximately 60 per cent of the total), thermal power 16,983.6 GWh (nearly 35 per cent) and other renewable energy sources (RES), including wind power, solar power, biogas and biomass, contributed a combined 2,885.5 GWh (6 per cent) (Figure 2).[6]

Figure 2. **Annual Electricity Generation by Source in Peru in 2020 (GWh)**



Source: COES[6]

The difference between installed and available capacity, as well as the low electricity generation by thermal power relative to installed capacity, is explained by the fact that significant reserve capacities of thermal power exist in Peru that are generally not utilized, as the country continues to work towards reducing its reliance on fossil fuels and prioritizing power generation from RES, including hydropower. Notably, despite an overall decrease in generation between 2019 and 2020, caused in large part by the impact of the COVID-19 pandemic, generation from RES including small hydropower (SHP) actually grew from 4,504.9 GWh in 2019 to 4,970.5 GWh in 2020, indicating a 10 per cent increase. The share of RES in annual electricity generation thus increased from 8.5 per cent in 2019 to 10.1 per cent in 2020.[6]

Access to electricity in Peru is near-universal, having improved dramatically in recent years and reaching 98 per cent in 2019.[7] The number of connected users has increased from approximately 4,879,000 in 2009 to 7,614,000 in 2019 with peak demand rising accordingly, from 4,322 MW to 7,018 MW over the same period.[5] Peak demand increased again in 2020, amounting to 7,125 MW.[6] However, the electricity grid of Peru, the National Interconnected Electric System (SEIN), has not fully kept pace with the growth of generation capacity and demand.

The key public institution overseeing activities in the energy sector of Peru is the Ministry of Energy and Mines (MINEM), which develops the legal and institutional framework for activities in the sector. Additional agencies involved in the energy sector include:

- The Supervisory Agency for Energy and Mining Investment (OSINERGMIN), which among other functions sets and regulates electricity tariffs;
- The Electrical Infrastructure Administration Enterprise (ADINELSA), a coordination agency working with local and regional authorities to provide rural electrification services; and
- The Committee for the Economic Operation of the Electric System (COES), a technical entity comprising the owners of generation plants and transmission systems, which coordinates the operation and development of the national grid (SEIN) and manages the short-term market.[8]

The electricity sector in Peru has undergone several major reforms in the last 30 years, starting with the Electricity Concessions Law of 1992, which set up a new tariff structure for end users and unbundled generation, transmission and distribution activities in the sector, allowing private entities to play a larger role. In 2006, the Law for Efficient Generation Development was adopted, aiming to guarantee efficient generation of electricity as well as to reduce the vulnerability of the electricity system to price volatility and blackouts. The law promoted longer tenders and contract terms in order to support investment in large-scale generation, implemented further tariff changes and established two new types of transmission systems—one for supplementary transmission and one for guaranteed transmission.[9] The key document outlining the ongoing and planned development of the electricity sector of Peru is the National Rural Electrification Plan 2016–2025. Among other targets, the plan aims to provide electricity access to 3.3 million people by 2025.[10] Efforts are being made to increase access to electricity via auctions for solar photovoltaic systems, grid extension, mini-grids with hydropower, solar and wind power.[8]

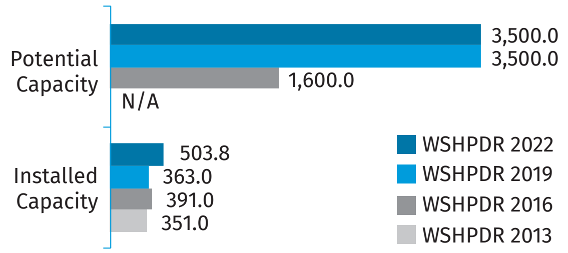
The Office for Tariff Regulation (GART), part of OSINERGMIN, regulates transmission and distribution tariffs.[8] The average tariffs have increased from 0.083 USD/kWh in 2009 to 0.103 USD/kWh in 2019.[5] Tariffs vary across economic sectors and regions.[6]

SMALL HYDROPOWER SECTOR OVERVIEW

In Peru, SHP plants are defined as hydropower plants with an installed capacity of up to 20 MW. As of 2020, there were 46 SHP plants operating in the country with a total installed capacity of 503.8 MW.[11]

In 2016, MINEM carried out an evaluation of the country's hydropower potential, identifying 380 potential SHP sites with a combined installed capacity of 3,311 MW.[12] While it is not known which of the sites identified in the study have been developed since 2016, total potential capacity for SHP in Peru, including existing plants, is estimated at 3,500 MW. This suggests that as of 2021, approximately 14 per cent of the potential capacity has been developed. Relative to the *WSHPDR 2019*, installed capacity has increased by almost 39 per cent due to the commissioning of many new SHP plants in recent years, while potential capacity has remained the same due to lack of more recent rigorous assessments (Figure 3).[9]

Figure 3. **Small Hydropower Capacities in the WSHPDR 2013/2016/2019/2022 in Peru (MW)**



Source: OSINERGMIN,[11] *WSHPDR 2019*,[9] MINEM,[12] *WSHPDR 2013*,[13] *WSHPDR 2016*[14]

In terms of the regional distribution of SHP plants in Peru, the largest number of plants can be found in the regions of Arequipa (9 plants), Junín (9 plants) and Lima (8 plants), while the largest installed capacity of SHP is found in Junín (121.2 MW) and Lima (87 MW), which account for approximately 47 per cent of the installed capacity of SHP nationwide (Figure 4).[11] This distribution of installed capacity coincides with electricity demand, as Junín and Lima are two of the country's most heavily populated regions. A list of 20 most recently commissioned SHP plants is displayed in Table 1.

As of 2021, there were 24 ongoing SHP projects in Peru, with a total planned installed capacity of 288.5 MW. The projects all have concession contracts, with construction to be completed by 2024, but several have been delayed indefinitely and are currently undergoing further negotiations.[15,16] Several ongoing SHP projects are listed in Table 2.

RENEWABLE ENERGY POLICY

Support for the development of RES in Peru was established by Legislative Decree No. 1002 for the Promotion of Investment for Electricity Generation with the use of Renewable Energy of 2008. The decree identified the development of generation of electricity from RES as a public necessity and mandated the formulation of a National Renewable Energy Development Plan, which would set a five-year rolling target share of total generation to be met by RES, excluding large and small hydropower. The subsequent plan set a 5 per cent target for generation from RES by 2013 (generation share from non-hydropower RES amounted to approximately 6 per cent in 2020).[6,8,17]

Also in 2008, the Government issued the Regulation for Electricity Generation with Renewable Energy, which determined the administrative procedures for renewable energy auctions and the granting of concessions for RES development, outlined the requirements for submitting, evaluating and awarding bids and set marketing procedures and RES tariffs.[8]

Financial and regulatory support measures for RES development include the following:

- An annual maximum accelerated depreciation of 20 per cent on income tax for all RES projects, which applies to machinery, equipment, installation, operation and maintenance work for grid-connected plants;
- Power producers using RES are entitled to early recovery of the value-added tax (VAT) from electricity sales;
- For SHP projects under 10 MW of installed capacity, permits are applied for at the regional level near the project site and no Environmental Impact Assessment (EIA) is required; instead, the developer must file a non-environmental impact commitment document.[8,9,18]

COST OF SMALL HYDROPOWER DEVELOPMENT

Previous studies concluded that a project cost of approximately 850–1,000 USD/kW is the upper limit for the market viability of SHP development in Peru, based in part on the low cost of electricity generation from the country's abundant natural gas reserves. With the generation price increased to 0.056 USD/kWh, a project cost of 1,400 USD/kW would be potentially viable.[9,19] However, most recently constructed SHP plants have exceeded these upper limits by a wide margin, with project costs ranging from 1,200 USD/kW to 4,200 USD/kW.[11]

FINANCIAL MECHANISMS FOR SMALL HYDROPOWER PROJECTS

The primary mechanism for financing RES and other energy projects in Peru is project finance, whereby the project's revenues from operation are expected to be sufficient for repayment. The auction system for electricity generation projects provides an annual income guarantee, established by the tariff awarded on a project-by-project basis during the public auction and multiplied by the expected annual energy deliveries to the grid, with priority of dispatch and access to transmission and distribution networks likewise guaranteed. Power Purchase Agreements (PPAs) are signed for a period of 20 years.[8]

The Government of Peru has promoted the Clean Development Mechanism (CDM) first established under the Kyoto Protocol to attract international investment into the country's RES sector. In 2020, Peru and Switzerland signed a bilateral carbon offset agreement that will finance green energy development in Peru through additional levies issued by motor fuel importers in Switzerland, counting towards the latter country's virtual emissions reduction.[19,20]

EFFECTS OF CLIMATE CRISIS ON SMALL HYDROPOWER DEVELOPMENT

The impact of El Niño results in a great variability in the rainfall intensities in Peru, especially along the northern coast during the summer months. In 1998, extreme weather events caused by El Niño resulted in damage to the energy sector estimated at USD 166 million, of which 67 per cent corresponded to damage to hydropower infrastructure.[21] Similarly, during the coastal El Niño event of 2017, multiple hydropower plants in Peru incurred damage to their infrastructure, including the Callahuanca hydropower plant, which required two years of work and USD 45 million of investment for subsequent reconstruction.[22] With the intensity of El Niño increasing due to the ongoing global climate change, the hydropower sector in Peru can be expected to incur additional costs from related extreme weather events in the future.[23]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

Peru is a country rich in RES, but only a small fraction of this potential is currently used. While investment in the renewable energy sector has been growing, the development of RES, including SHP, continues to face several obstacles, including the following:

- High initial investment costs compared to thermal power plants;
- Lack of sufficient human capacity for operation and maintenance and high cost of training;
- Limited transport and construction infrastructure impeding projects;
- Environmental concerns;
- Limited awareness in the financial sector of the RES market and profitability of RES projects, as well as project evaluation criteria and regulations. This leads to a situation where banks require external technical support to assess RES projects.

Enablers for SHP development include:

- The country's considerable untapped SHP potential;
- The experience and commitment of the country to hydropower development in general;
- Support offered in the form of long-term PPAs at guaranteed prices available for RES projects, as well as certain tax rebates.

Suriname

Laura Stamm, International Center on Small Hydro Power (ICSHP)

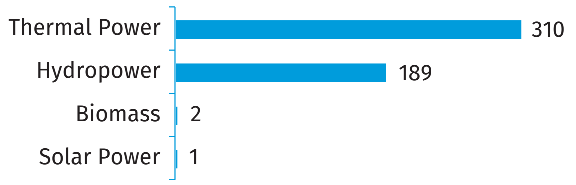
KEY FACTS

Population	586,634 (2020)[1]
Area	163,820 km^2 [2]
Topography	Suriname is located on the north-eastern coast of South America and the large majority of its territory is covered with tropical rainforest. The country can be divided into four ecological zones. The New Coastal Plain in the north is a flat swampland on the Atlantic coastline. Just south of this is the Old Coastal Plain, which is mostly flat but with some ridges and hills. The Wilhelmina Mountains are located in the central to southern region and has the highest altitudes. Juliana Top is the highest peak in the country at 1,230 metres. The Sipaliwini Plain is a savanna region that stretches down to the southern border with Brazil.[3]
Climate	Suriname has a tropical climate with dry and rainy seasons. Temperatures mostly remain between 21 °C and 32 °C. However, the coastal north usually only experiences the upper half of the range and the central and southern highlands experience the whole range. The driest period is between August and December, whereas the wettest season is between April and August. January to February is considered a short and minor wet season, while March to early April is a short and minor dry period.[3,4]
Climate Change	Over the past three decades, average rainfall in Suriname has shown an increase in all areas of the country and over a 500 mm per decade increase in the south-western region. However, it is predicted that by the end of the century overall rainfall will decrease, especially in the north. Temperatures have shown to increase in the northern region over the past three decades, but decrease in the south. Over the course of the next decades, average temperatures are expected to increase throughout the whole country by between 2 °C and 5 °C. Extreme weather events are also expected to increase.[4]
Rain Pattern	Rainfall varies between regions and periods of the year, but average rainfall is between 1,900 mm and 2,400 mm per year. Throughout the country, rainfall is highest between late April and early August when severely heavy rains are a common occurrence. Average rainfall in May, the wettest month, is approximately 325 mm.[3,4]
Hydrology	There are seven major rivers in Suriname, which drain northwards towards the Atlantic Ocean. These are the Maroni, Corentyne, Commewijne, Suriname, Saramacca, Coppename and Nickerie. There are no rivers that cross into or out of Suriname. The rivers mentioned are on the border of the country but not considered to be border rivers. Nani Lake is the only natural fresh water lake, with total dam capacity estimated at 20 km^3. Brokopondo Lake is the largest lake in the country covering 1,560 km^2. Swamps, which are characterized by stagnant water, dense tropical forest and large amounts of decaying vegetation, cover approximately 60 per cent of the Coastal Plains.[5]

ELECTRICITY SECTOR OVERVIEW

In 2020, the total installed capacity of Suriname was approximately 502 MW. The country's energy mix consisted of 310 MW (just under 62 per cent) from fossil fuels, 189 MW (38 per cent) from hydropower, 2 MW from biomass and 1 MW from solar power (Figure 1).[6] The 189 MW of hydropower capacity comes from the Afobaka plant, which was originally built by and ran by Suralco, a foreign private mining company, but was given to the Government of Suriname upon the company leaving the country in 2019.[7]

Figure 1. **Installed Electricity Capacity by Source in Suriname in 2020 (MW)**



Source: OLADE[6]

In 2020, total electricity generation was 2,368 GWh. Thermal power generated 1,252 GWh (53 per cent), hydropower generated 1,105 GWh (46 per cent) and the remaining 1 per cent comprised 9 GWh from solar power and 2 GWh from biomass (Figure 2).[6] Due to inefficient infrastructure, loss of electricity is considered an issue of concern for Suriname and in 2019 losses amounted to 452 GWh, or 19 per cent of total electricity generated.[8]

Figure 2. **Annual Electricity Generation by Source in Suriname in 2020 (GWh)**

Source: OLADE[6]

The electrification rate in Suriname in 2019 was just under 98 per cent. More than 99 per cent of the urban population has access to electricity, whereas slightly less than 96 per cent of the rural population does.[9] In many rural areas, the most common source of energy is diesel generators, which typically only provide the communities with electricity for four to six hours per day.[10]

The two major national companies that are responsible for the generation, distribution and transmission of electricity are the State Oil Company of Suriname (Staatsolie) and the Suriname Energy Company (EBS). Originally, Staatsolie was an oil producing company and generated exclusively thermal energy, but since 2007 has sought to diversify into renewable energy with the creation of its renewable energy unit. After first diversifying into biomass in 2010, it now also generates hydropower since the transfer of control of the Afobaka hydropower plant.[11] EBS is responsible for the distribution and transmission of electricity. EBS's current major focus in improving the quality of electricity transmission and distribution infrastructures is to decrease losses and increase energy stability in the country.[10]

Table 1. **Average Electricity Tariffs by Consumer Type in Suriname**

Type of consumer	*Usage*	*Tariff (USD/kWh)*
Residential	Up to 800 kWh	0.056
	Above 800 kWh	0.087
Non-residential	Up to 2,600 kWh	0.056
	Above 2,600 kWh	0.087
Street lighting	N/A	0.079

Source: EAS[12]

Before the implementation of the 2016 Electricity Act, the average retail electricity tariff in Suriname was 0.04 USD/kWh. This was one of the lowest tariffs in Latin America and the Caribbean and was supported by Government subsidies. In order to better regulate appropriate electricity tariffs, the Energy Authority of Suriname (EAS) was created and began operating in 2020. The details of the average tariff for each type of consumer per Decree No. 88 of 2021 are given in Table 1.[12]

SMALL HYDROPOWER SECTOR OVERVIEW

There is no official country definition for small hydropower (SHP) in Suriname. In this chapter, SHP is defined as the plants with a capacity of less than 10 MW. It is estimated that the total potential capacity of hydropower in the country is 2,419 MW.[13] Based on previously planned projects, SHP potential is at least at 2.7 MW.[14] Plans for achieving at least 2.7 MW of SHP installed capacity were included in the initial plan of the Development of Renewable Energy, Energy Efficiency and Electrification of Suriname Project. However, due to budget limitations, the Ministry of Natural Resources submitted a restructuring proposal on 7 April 2017 and it was agreed that the Rural Small Hydro Project section would be cancelled.[15]

There have been some SHP plants that were in operation within the country in the past, but all have since closed. Poeketi was the first SHP plant constructed in Suriname. It was completed in 1981 and supplied 50 kW to the nearby community until it shut down in 1987.[16] In 2005, construction began on the Gran Olo Sula plant with the goal capacity of 300 kW, but due to flooding and financial issues, it was not completed until 2017, with a lower capacity than planned and was in operation for five days before it was shut down.[17] Compared to the *World Small Hydropower Development Report (WSHPDR) 2019*, SHP installed capacity decreased based on more accurate data, whereas the potential remained unchanged (Figure 3).

RENEWABLE ENERGY POLICY

The National Energy Plan of 2013–2033 was one of the earliest official declarations of the country's interest in expanding renewable energy. Initiatives stated in the plan include goals to bring solar power and SHP to remote areas in the southern region as well as general interest to consider wind power as a possibility to explore.[19] The Policy Development Plan 2017–2021 further stresses the importance of renewable energy and discusses the need for innovative business models to feasibly bring it into the remote interior of the country. It suggests that public-private partnerships could be a key to achieve this.[20]

In 2016, the first comprehensive energy-related legislation was enacted. The Electricity Act of 2016 set out to improve the technical and financial situation of the power sector. The aim of this act was to create an energy regulatory authority, deal with the issue of overly low electricity tariffs by recommending a reduction in subsidies, allow for privatizations and to state the importance of attracting more investment into renewable energy.[21] The act created the EAS to oversee the tariffs of the country's energy sector. The specifics of how tariffs will be calculated by the EAS were published in the subsequent Electricity Sector Plan 2019–2023.[22] The act also mandates EBS to hold renewable energy tenders under the supervision of the EAS and obligates the company to purchase all solar and wind power generated by respective plants. Furthermore, it gives consumers the possibility of generating their own electricity using a net metering system that requires that the surplus electricity generated is fed back into the national grid. This amount cannot exceed total consumption for the year.[10,21]

The Environmental Framework Act of 2020 addresses appropriate environmental management. It includes the legal framework and procedures for environmental impact assessments and created the National Environmental Authority (NMA) to oversee this. The aim of this act was to more closely align the legal framework of the country with global environmental standards and to demonstrate commitment to international agreements such as the Paris Agreement.[22]

BARRIERS AND ENABLERS FOR SMALL HYDROPOWER DEVELOPMENT

The following barriers are particularly critical for SHP development in Suriname:

- Lack of funding, exemplified by the numerous cases of plans to develop projects being cancelled or plants being shut down soon after construction;
- Lack of local technical knowledge and skills in SHP development;
- High setup costs, in part due to the absence of road infrastructure leading to remote villages.

The following enablers may incentivize SHP development in Suriname:

- Electricity demand is continuously increasing and the installed capacity will soon have to increase to keep up;
- Over 100 villages do not have electricity for the entire day and depend on diesel generators and the monthly delivery of a finite amount of diesel to power them. SHP could greatly improve the quality of their electricity access and energy stability;
- SHP would also lessen the country's dependence on the one large hydropower plant, Afobaka.[20]

Uruguay

Cecilia Correa Poseiro and Arturo Alarcón, Inter-American Development Bank

KEY FACTS

Population	3,473,727 (2020)[1]
Area	176,215 km^2[2]
Topography	Uruguay has a low and slightly sloping topography with an average elevation of 116.7 metres above sea level. The relief is homogeneous, with two large structural areas: peneplains and plains. The peneplains are gently undulating reliefs that extend over most of the country's territory and contain rounded hills with a wide base, which are known as cuchillas and reach a maximum height of 514 metres. The plains extend in the peripheral areas of the Uruguay River, the River Plate and the Atlantic Ocean.[2,3]
Climate	Throughout its entire territory Uruguay has a homogeneous climate characterized as a temperate-humid one without a dry season. The average annual temperature is 17.5 °C, with a maximum average of 19 °C in the north and 16 °C on the Atlantic coast. The average temperature in winter is 11.5 °C and in summer 23.9 °C. The minimum temperatures occur in winter, generally in July; and the maximum temperatures occur in summer, generally in January.[3,4,5]
Climate Change	The average annual temperature is showing an increasing trend. The year 2017 was one of the warmest years on record with an average temperature of 18.7 °C, a maximum average of 24.1 °C and a minimum average of 13.2 °C.[6] Studies have also detected an increase in average precipitation between 1961 and 2017 with an average increase of 10 per cent in the north of the country and 15–20 per cent in the south.[7]
